

# **COMP6211: Trustworthy Machine Learning**

## **Lecture 3**

**Minhao Cheng**

# Exam

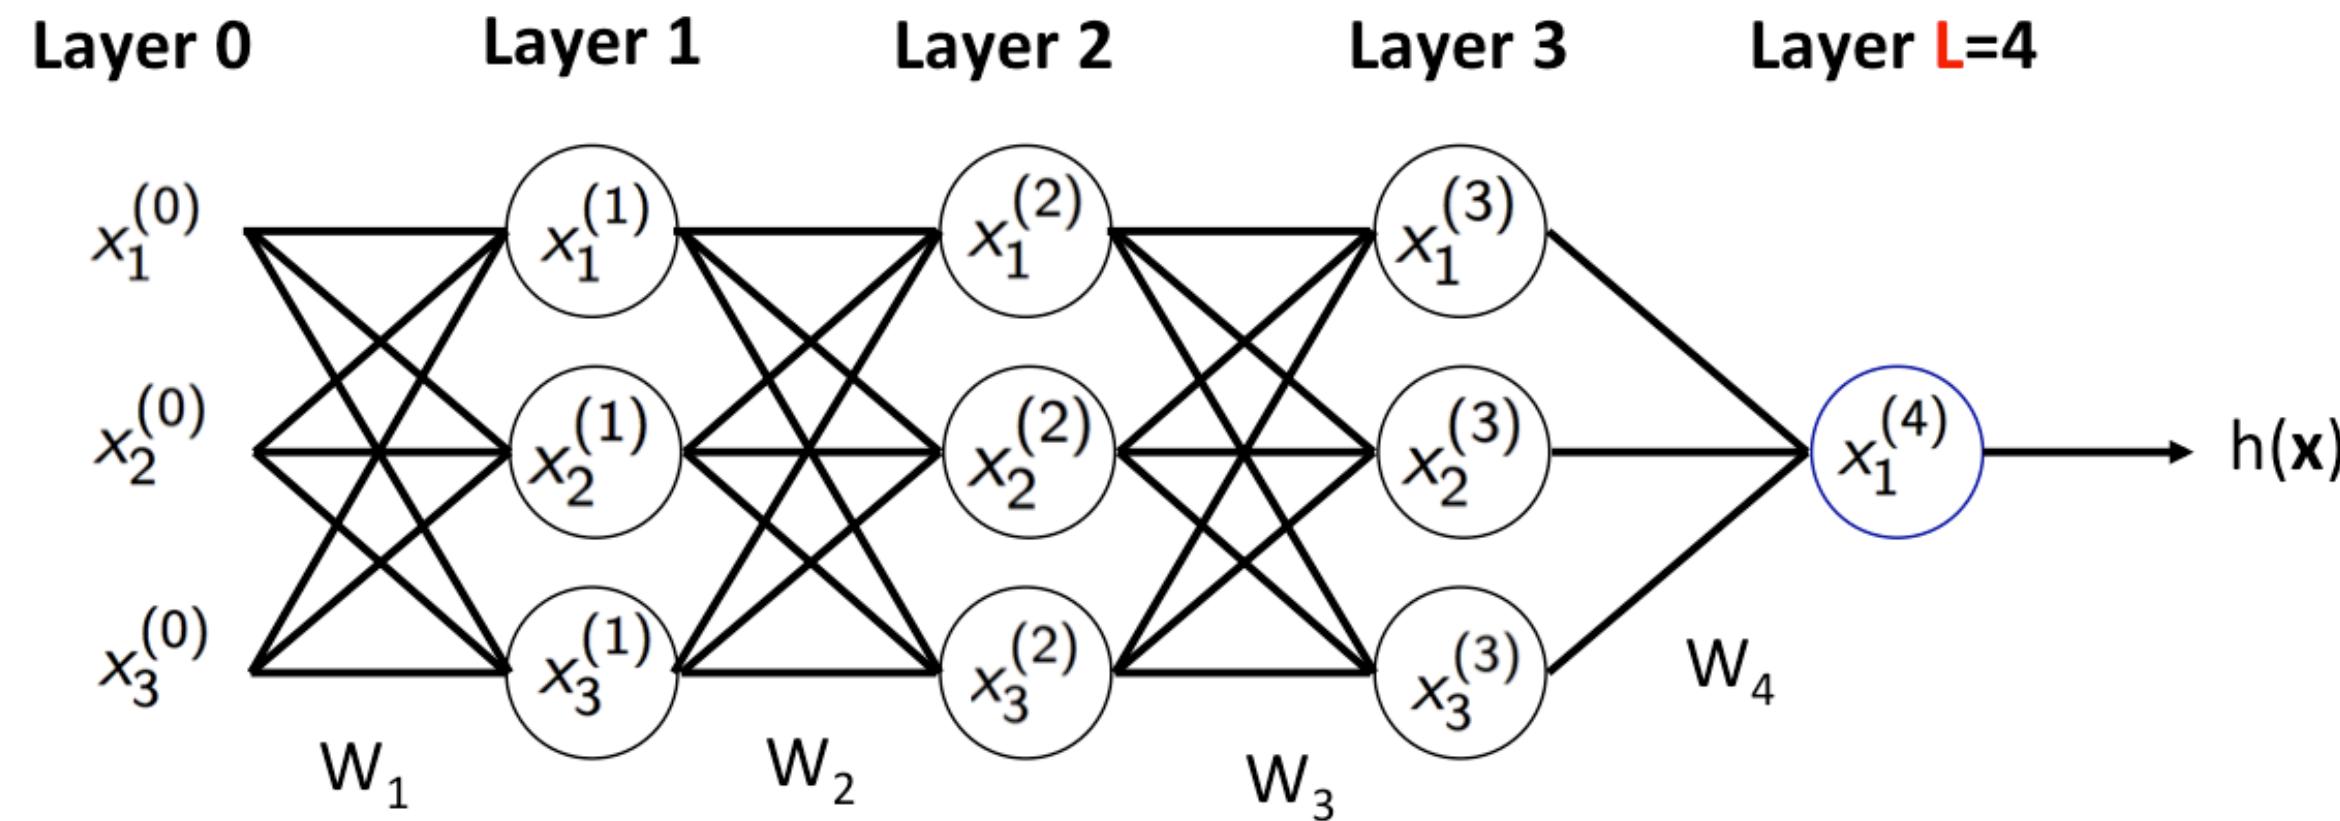

- On next Monday (Feb 20) during the class time
- 80 minutes
- Format:
  - True/False questions with reasons
  - Short answer questions
  - Problems (gradient derivation etc.)

# From week 3

- Paper presentation sign-up started today
- Start from Feb 20:
  - Reading summary
  - Paper presentation
  - Class notes & participation
- Project proposal will be due on Feb 24 (1/2 page)
  - Title
  - Proposed problem
  - Proposed methodology (optional)

# Convolutional Neural Network

## Neural Networks

$$\begin{aligned} h(\mathbf{x}) &= x_1^{(4)} = \theta(W_4 \mathbf{x}^{(3)}) = \theta(W_4 \theta(W_3 \mathbf{x}^{(2)})) \\ &= \dots = \theta(W_4 \theta(W_3 \theta(W_2 \theta(W_1 \mathbf{x})))) \end{aligned}$$

- Fully connected networks  $\Rightarrow$  doesn't work well for computer vision applications

# Convolutional Neural Network

## Convolution Layer

- Fully connected layers have too many parameters
  - $\Rightarrow$  poor performance
- Example: VGG first layer
  - Input:  $224 \times 224 \times 3$
  - Output:  $224 \times 224 \times 64$
  - Number of parameters if we use fully connected net:
    - $(224 \times 224 \times 3) \times (224 \times 224 \times 64) = 483 \text{ billion}$
  - Convolution layer leads to:
    - Local connectivity
    - Parameter sharing

# Convolutional Neural Network

## Convolution

- The convolution of an image  $x$  with a kernel  $k$  is computed as

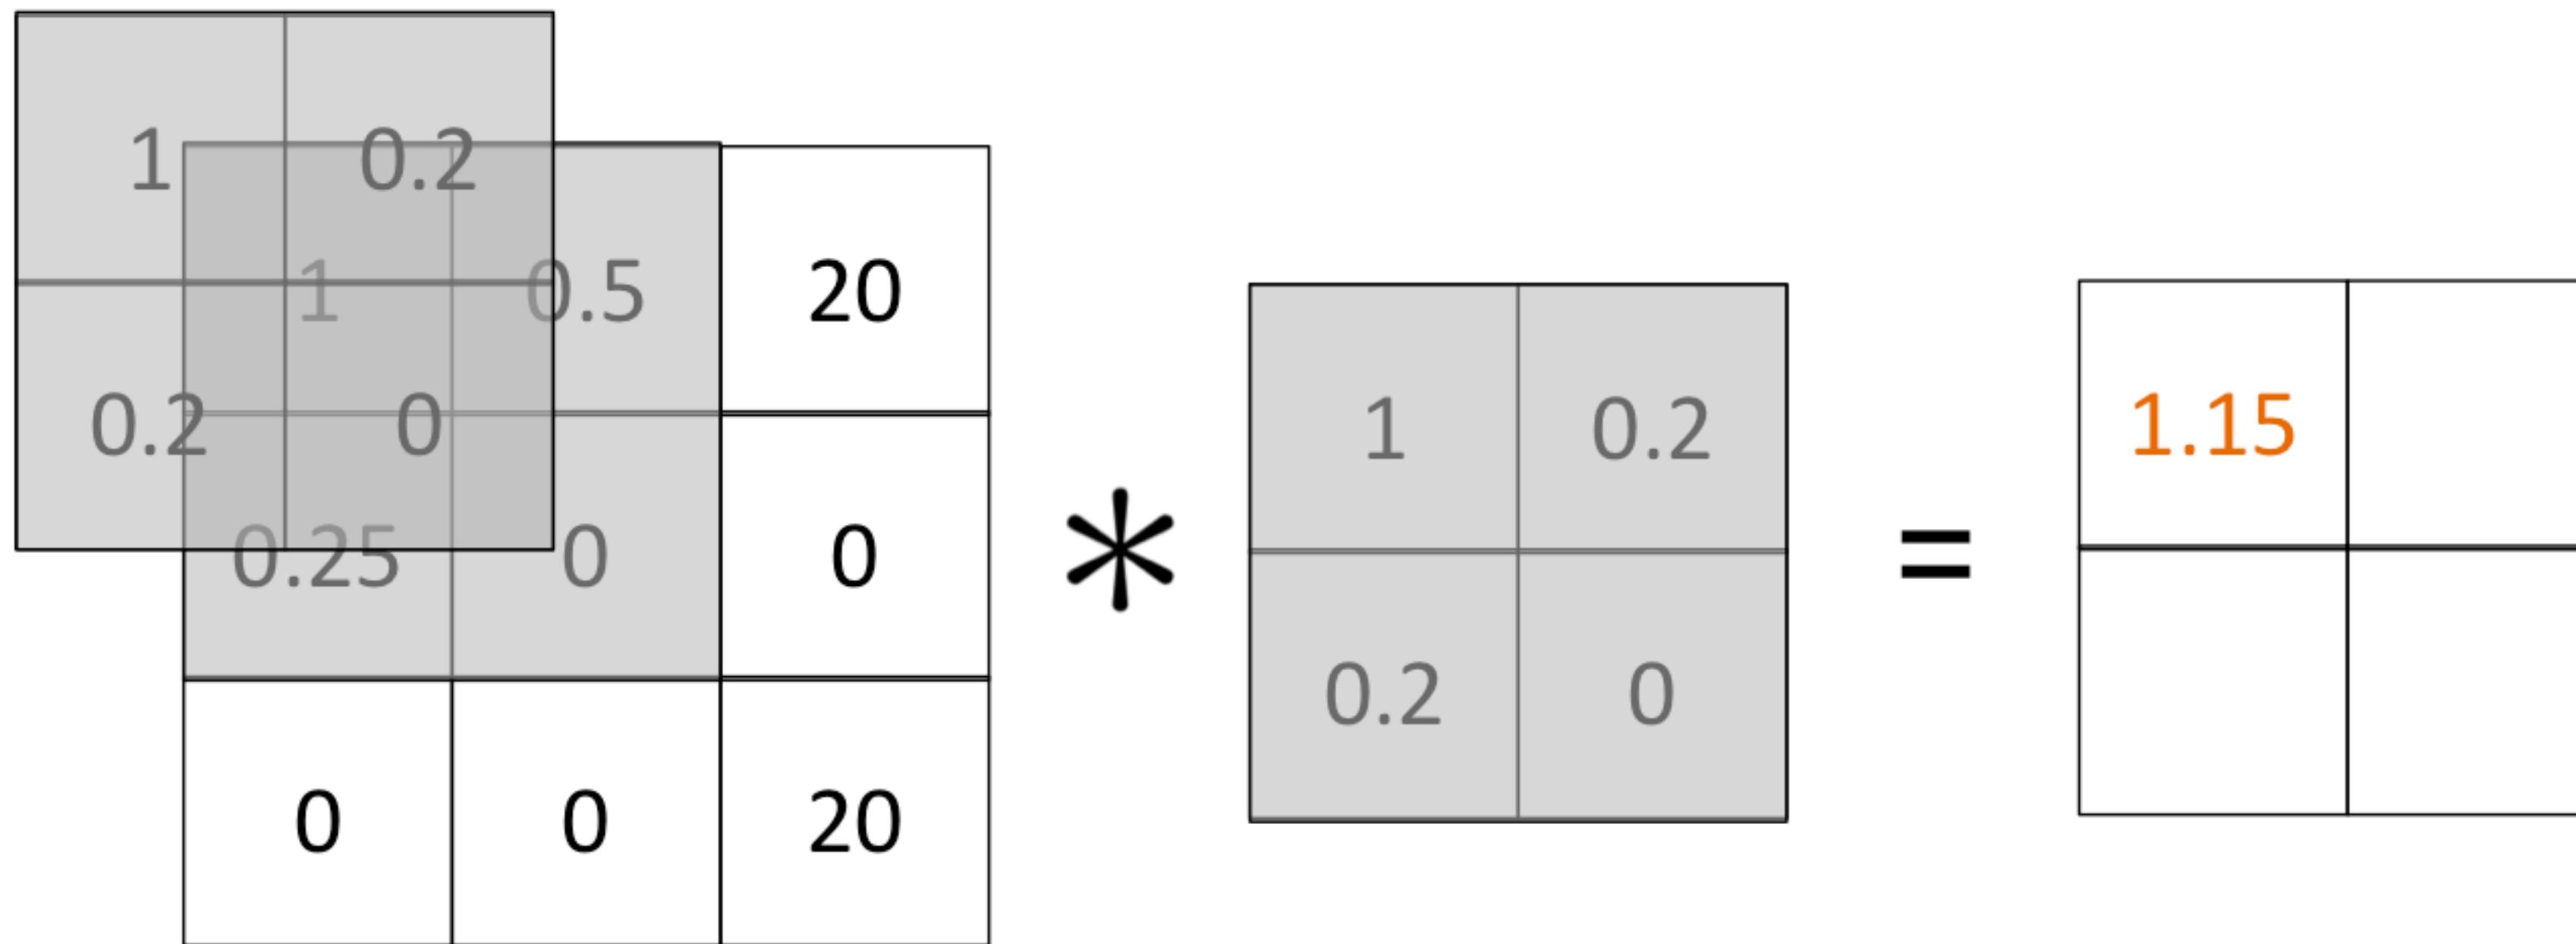

$$\bullet \quad (x * k)_{ij} = \sum_{pq} x_{i+p,j+q} k_{p,q}$$

$$\begin{array}{|c|c|c|} \hline 1 & 0.5 & 20 \\ \hline 0.25 & 0 & 0 \\ \hline 0 & 0 & 20 \\ \hline \end{array} * \begin{array}{|c|c|} \hline 1 & 0.5 \\ \hline 0.25 & 0 \\ \hline \end{array} = \begin{array}{|c|c|} \hline & \\ \hline & \\ \hline & \\ \hline & \\ \hline \end{array}$$

# Convolutional Neural Network

## Convolution

$$1*1 + 0.5*0.2 + 0.25*0.2 + 0*0 = 1.15$$

# Convolutional Neural Network

## Convolution

$$0.5*1 + 20*0.2 + 0*0.2 + 0*0 = 4.5$$

The diagram illustrates a convolution operation. On the left, a 3x3 input matrix is shown with values 1, 0.25, and 0 in its top row. The middle row contains 0, 0, and 20. The bottom row contains 0, 0, and 20. A 2x2 kernel matrix is shown to its right, with values 1, 0.5, 0.2, and 20 in its top row, and 0.2, 0, 0, and 0 in its bottom row. An asterisk (\*) indicates the multiplication of the input and kernel matrices. An equals sign (=) indicates the result. To the right of the equals sign is a 2x2 output matrix with values 1.15 and 4.5.

1	0.25	0	*	1.15
0	0	20	=	4.5

# Convolutional Neural Network

## Convolution

$$0.25*1 + 0*0.2 + 0*0.2 + 0*0 = 0.25$$

The diagram illustrates a convolution operation. On the left is a 3x3 input matrix with values: top row [1, 0.5, 20]; middle row [0.25, 0, 0]; bottom row [1, 0.2, 20]. A 2x2 kernel matrix is shown next to it, with values: top row [1, 0.2]; bottom row [0.2, 0]. The result of the convolution is a 2x2 output matrix on the right, with values: top row [1.15, 4.5]; bottom row [0.25, 0]. The calculation for the top-left value is highlighted in orange:  $0.25*1 + 0*0.2 + 0*0.2 + 0*0 = 0.25$ .

# Convolutional Neural Network

## Convolution

$$x * k_{ij}, \text{ where } W_{ij} = \tilde{W}_{ij}$$

# Convolutional Neural Network

## Convolution

- Element-wise activation function after convolution
  - $\Rightarrow$  detector of a feature at any position in the image

$$x * k_{ij}, \text{ where } W_{ij} = \tilde{W}_{ij}$$

$$\begin{matrix} 0 & 0.5 \\ 0.5 & 0 \end{matrix}$$

$$\begin{matrix} 0 & 0 & 255 & 0 & 0 \\ 0 & 0 & 255 & 0 & 0 \\ 0 & 0 & 255 & 0 & 0 \\ 0 & 255 & 0 & 0 & 0 \\ 255 & 0 & 0 & 0 & 0 \end{matrix}$$

$x_i$

$$\begin{matrix} 0.02 & 0.19 & 0.19 & 0.02 \\ 0.02 & 0.19 & 0.19 & 0.02 \\ 0.02 & 0.75 & 0.02 & 0.02 \\ 0.75 & 0.02 & 0.02 & 0.02 \end{matrix}$$

$$\text{sigm}(0.02 x_i * k_{ij} - 4)$$

# Convolutional Neural Network

## Learned Kernels

- Example kernels learned by AlexNet

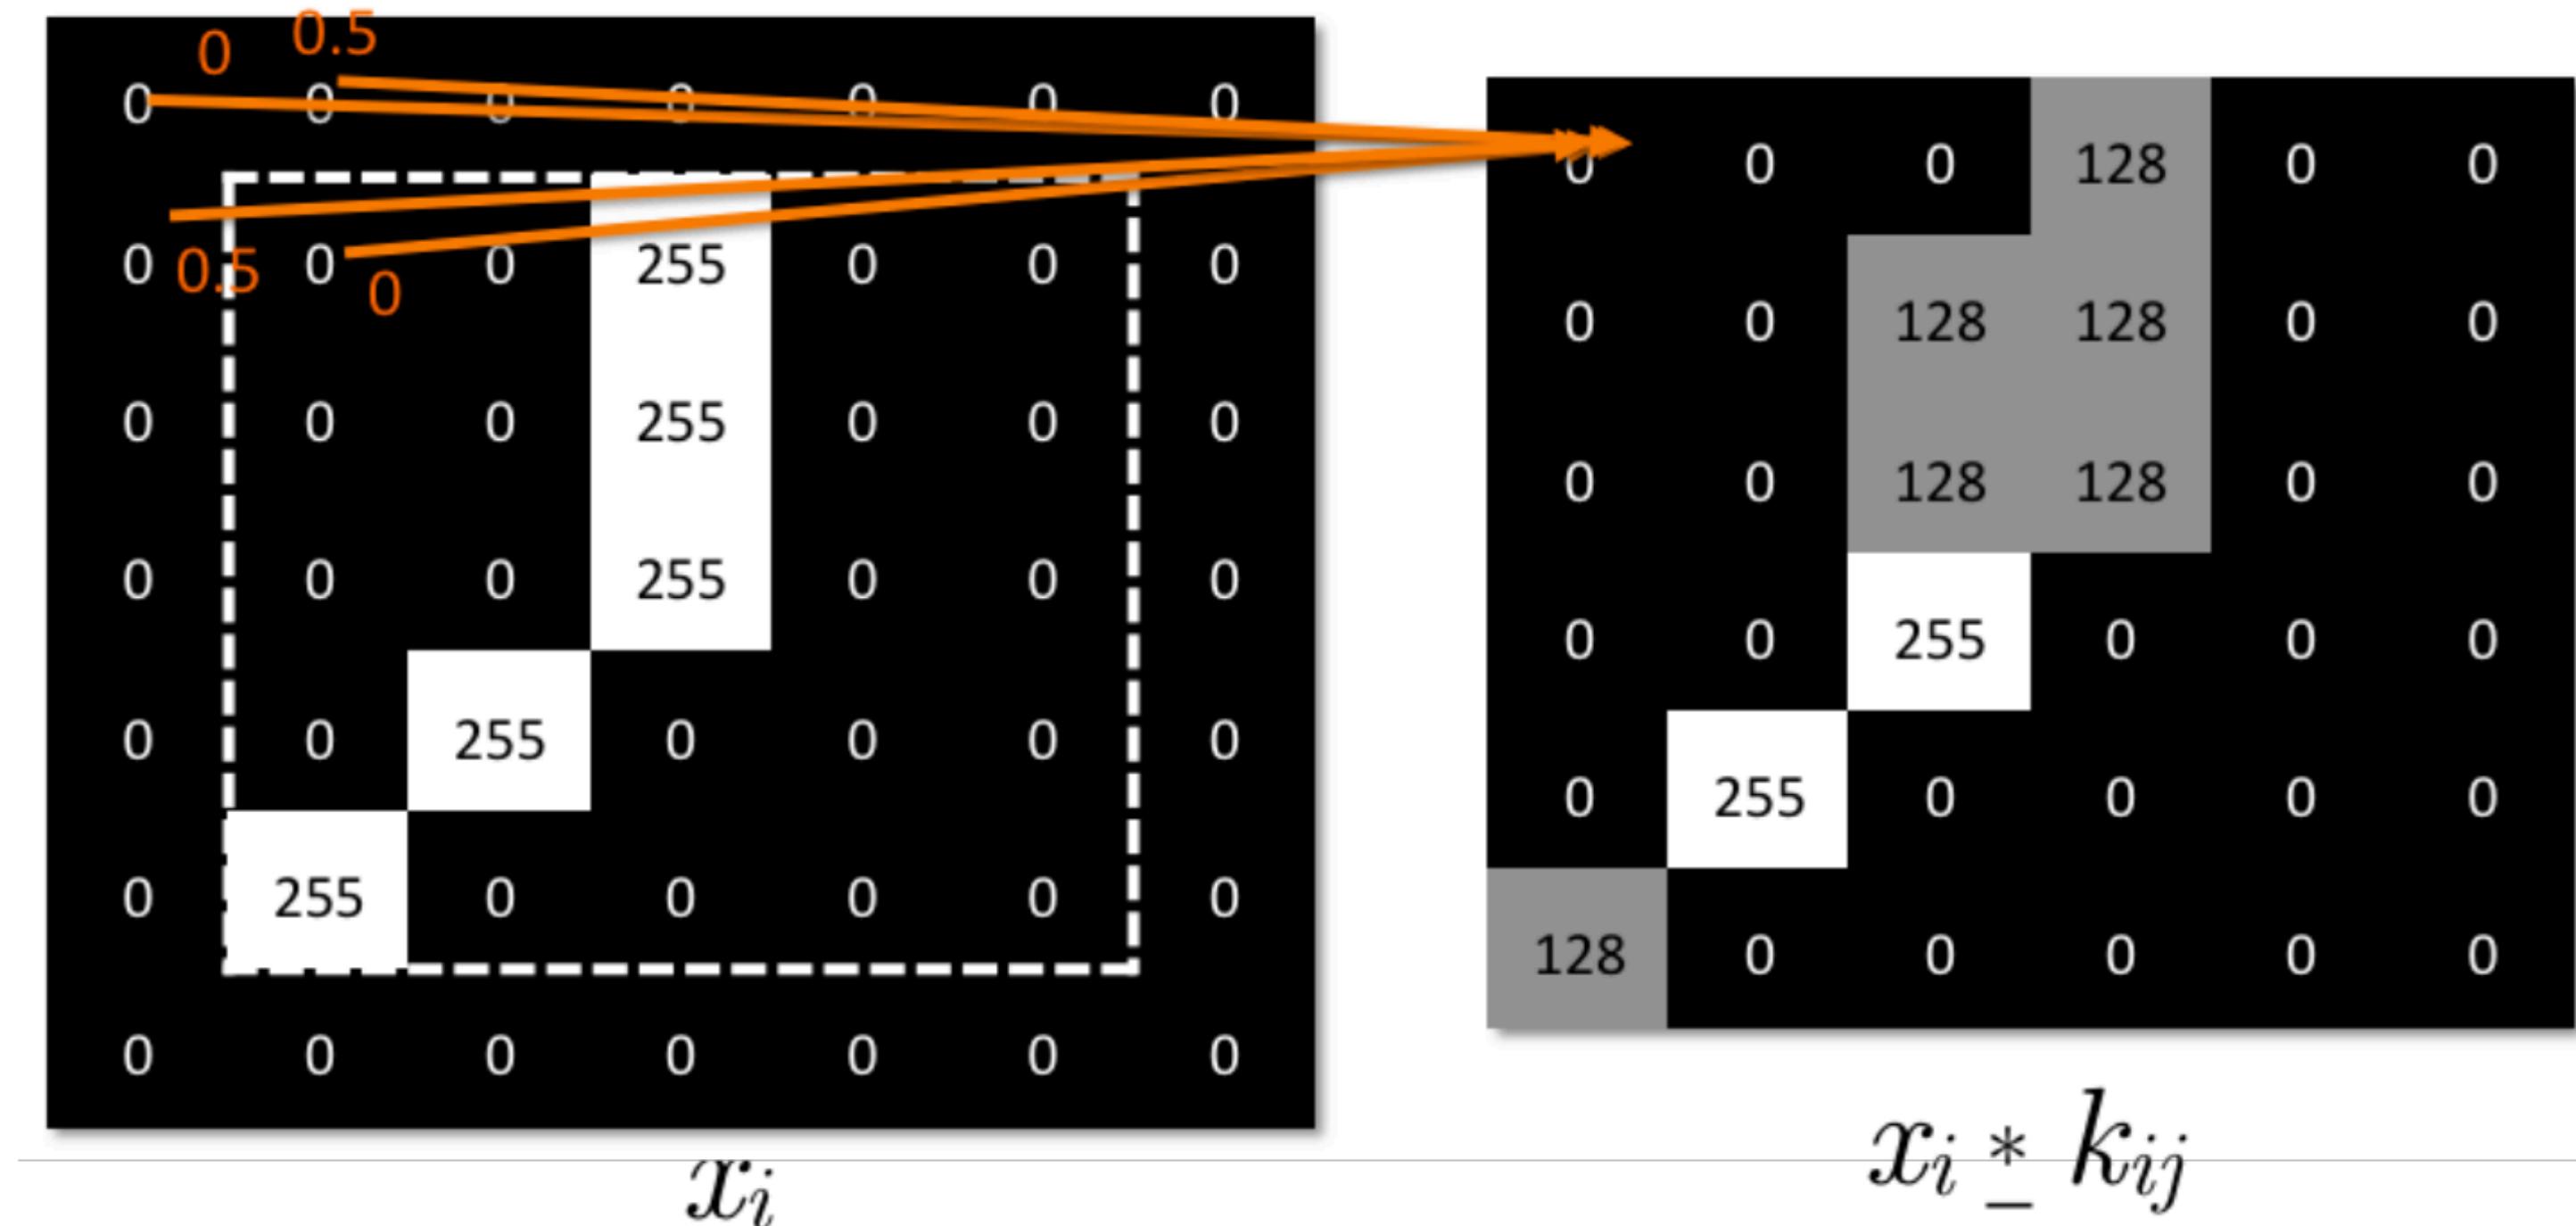

- Number of parameters:
  - Example:  $200 \times 200$  image, 100 kernels, kernel size  $10 \times 10$
  - $\Rightarrow 10 \times 10 \times 100 = 10K$  parameters

# Convolutional Neural Network

## Padding

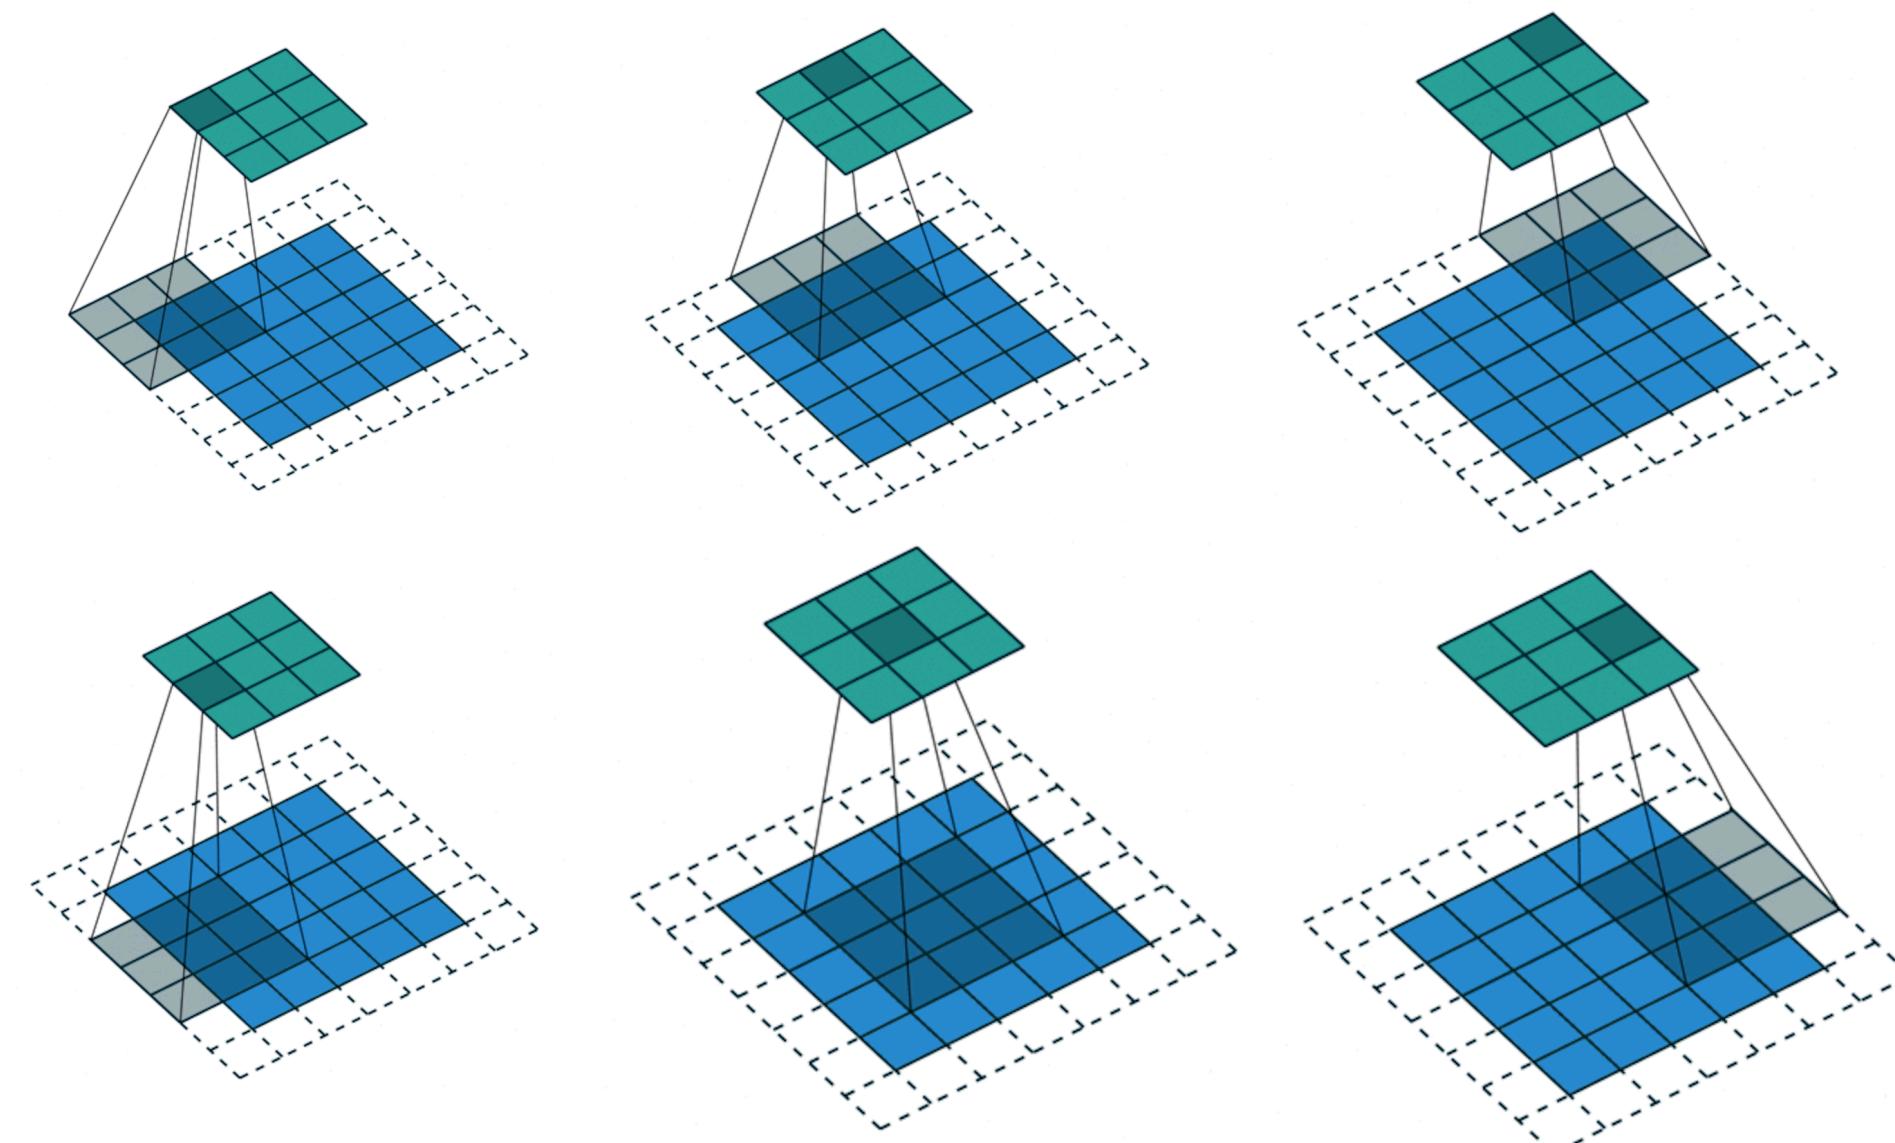

- Use **zero padding** to allow going over the boundary
  - Easier to control the size of output layer

# Convolutional Neural Network

## Strides

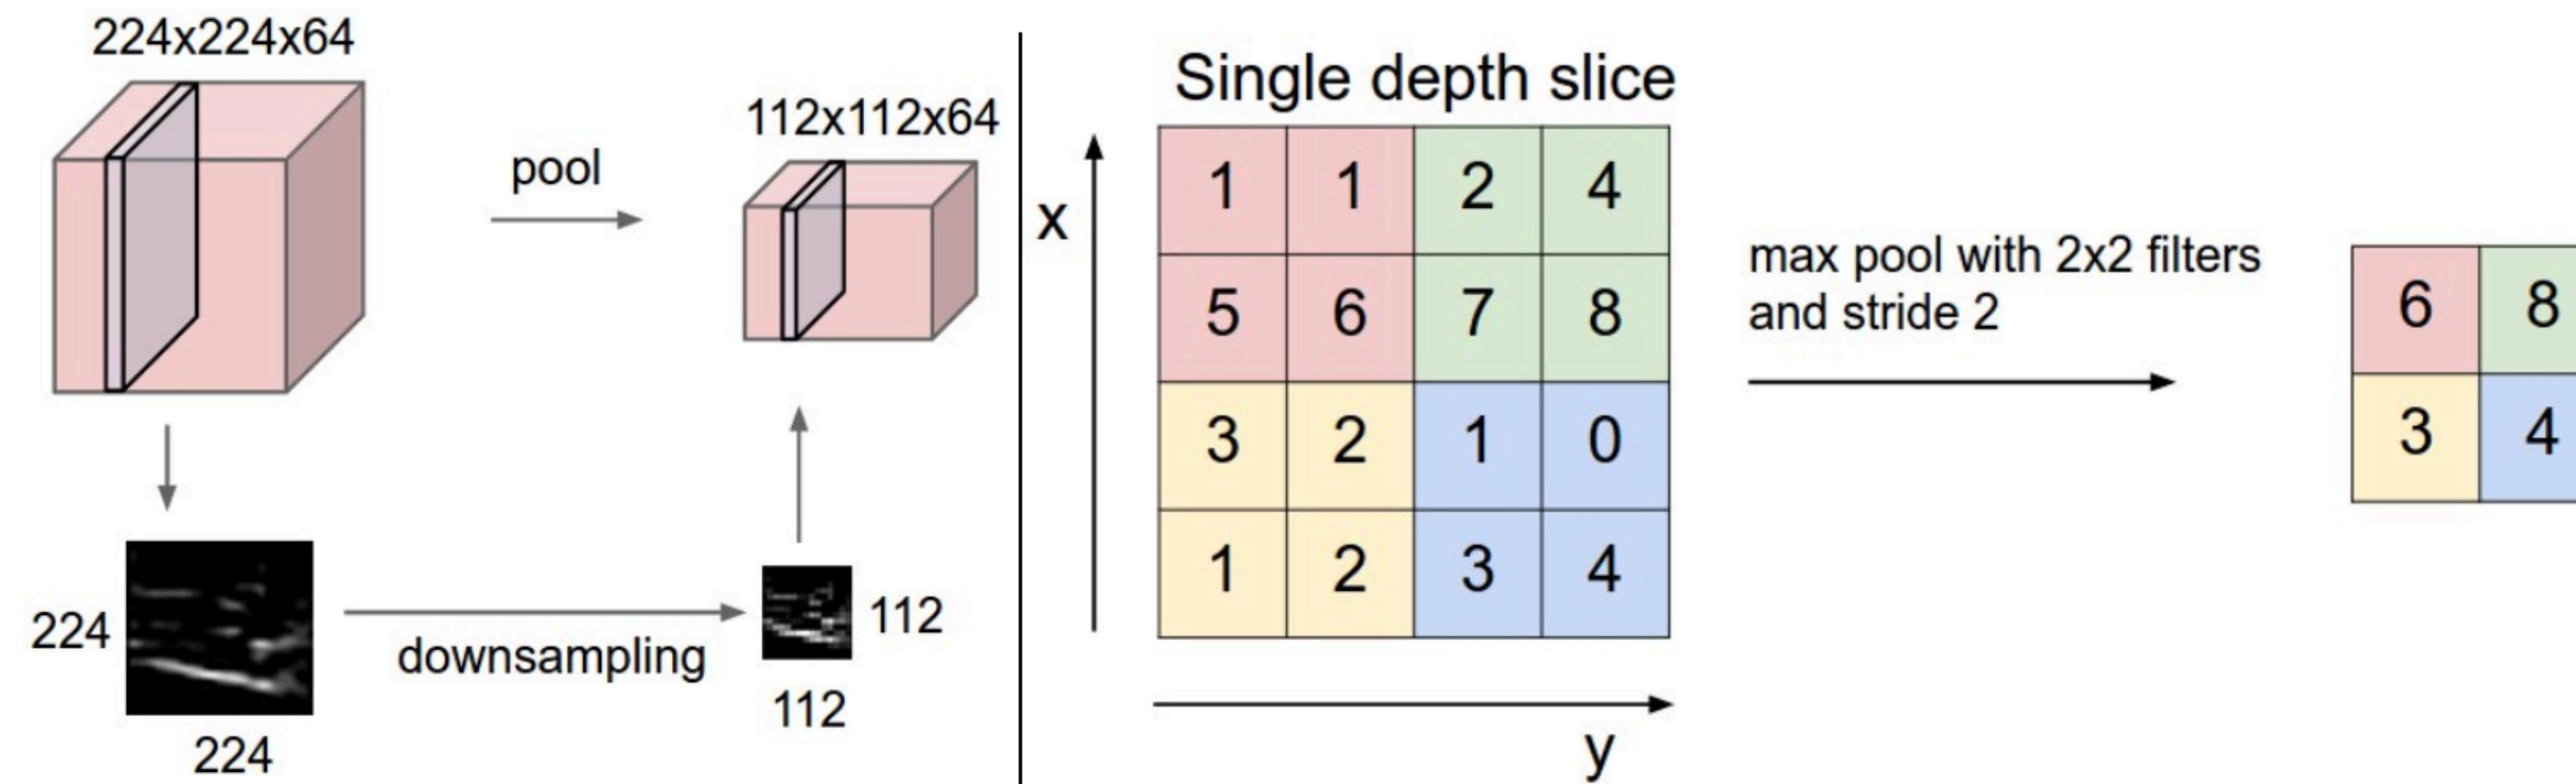

- Stride: The amount of movement between applications of the filter to the input image
- Stride (1,1): no stride

# Convolutional Neural Network

## Pooling

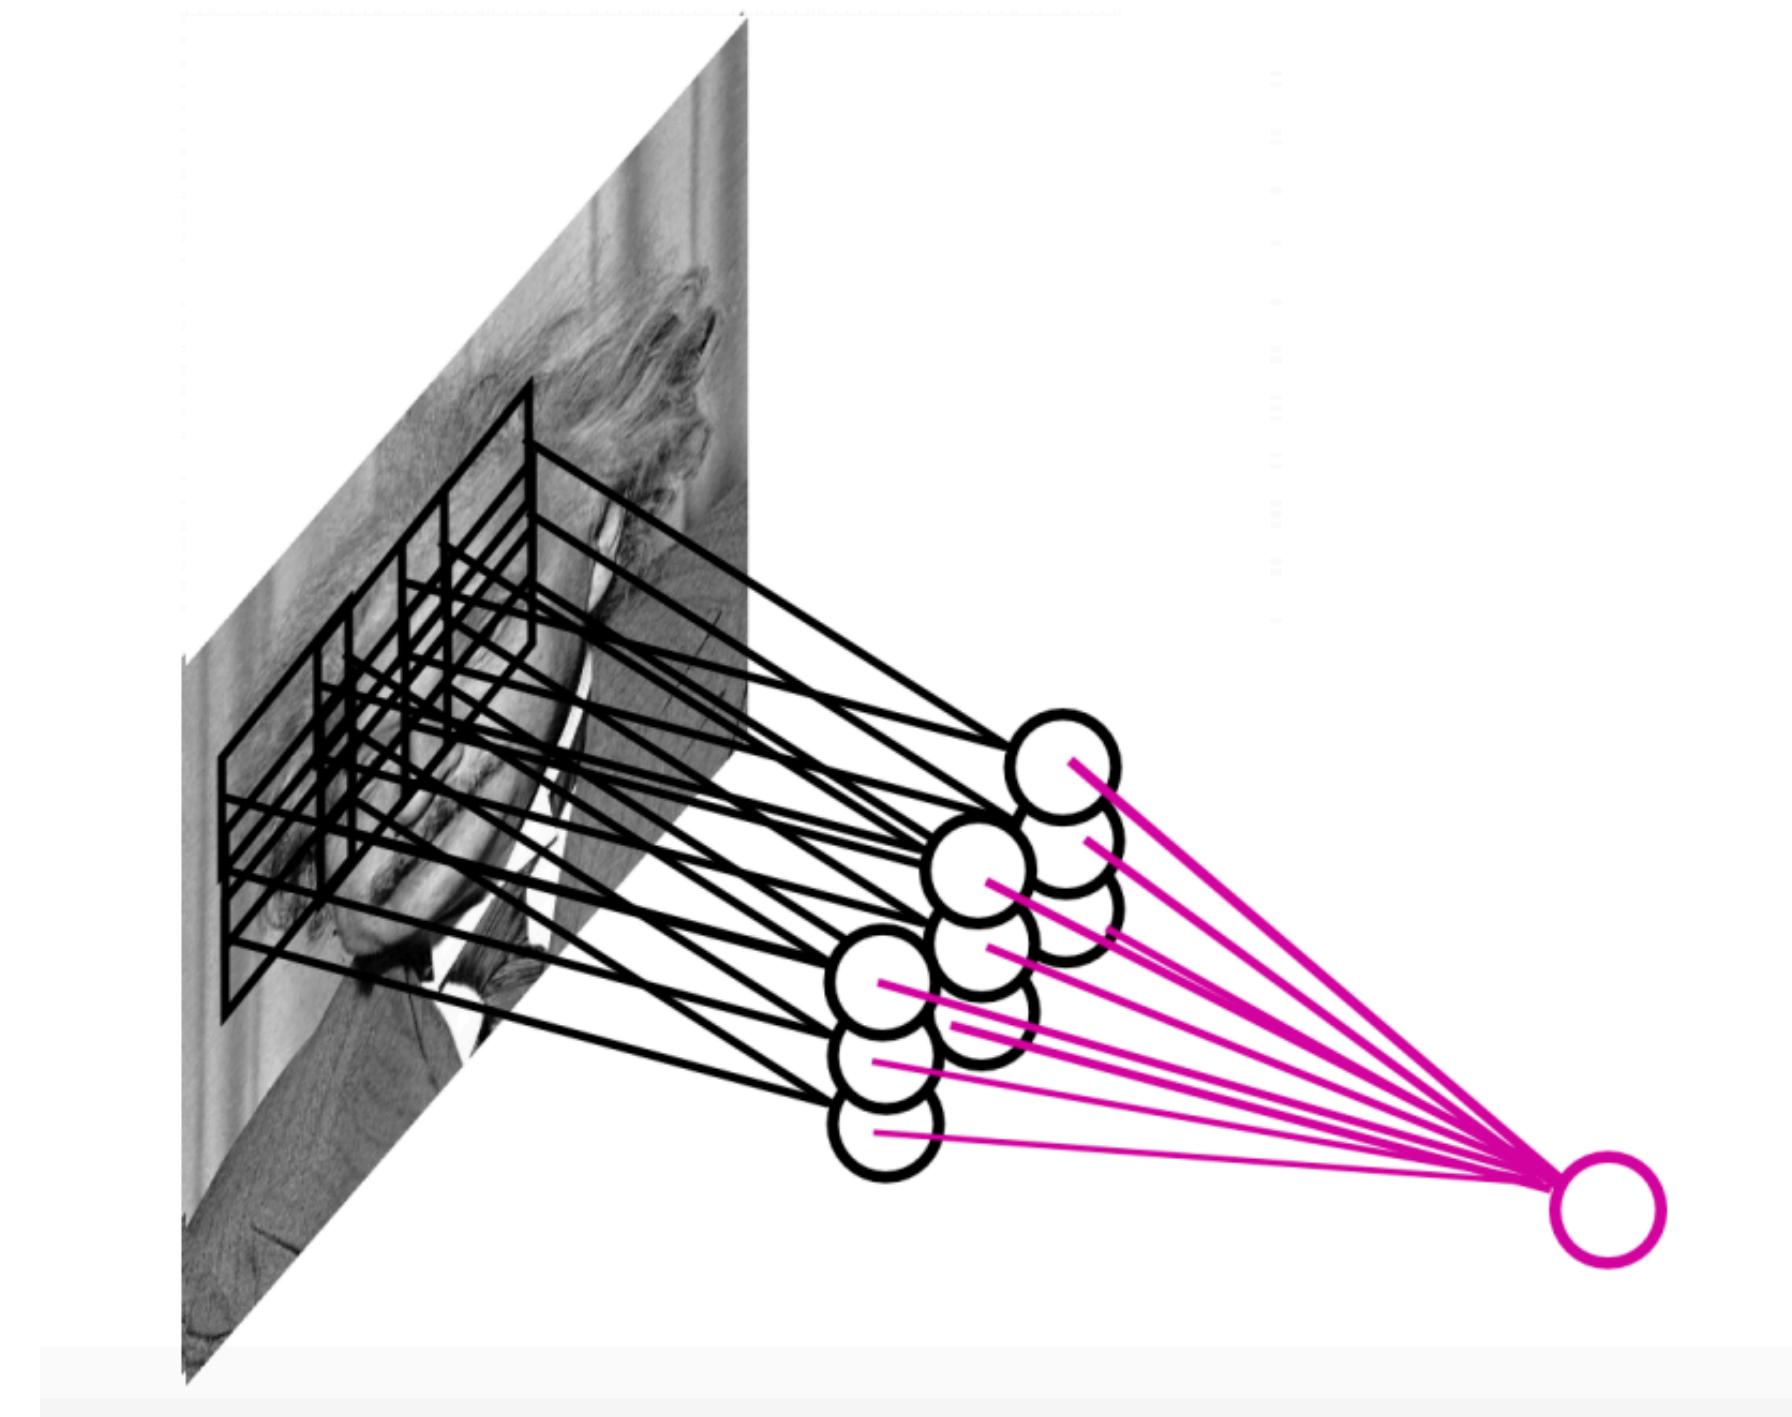

- It's common to insert a **pooling layer** in-between successive convolutional layers
- Reduce the size of presentation, down-sampling
- Example: **Max pooling**

# Convolutional Neural Network

## Pooling

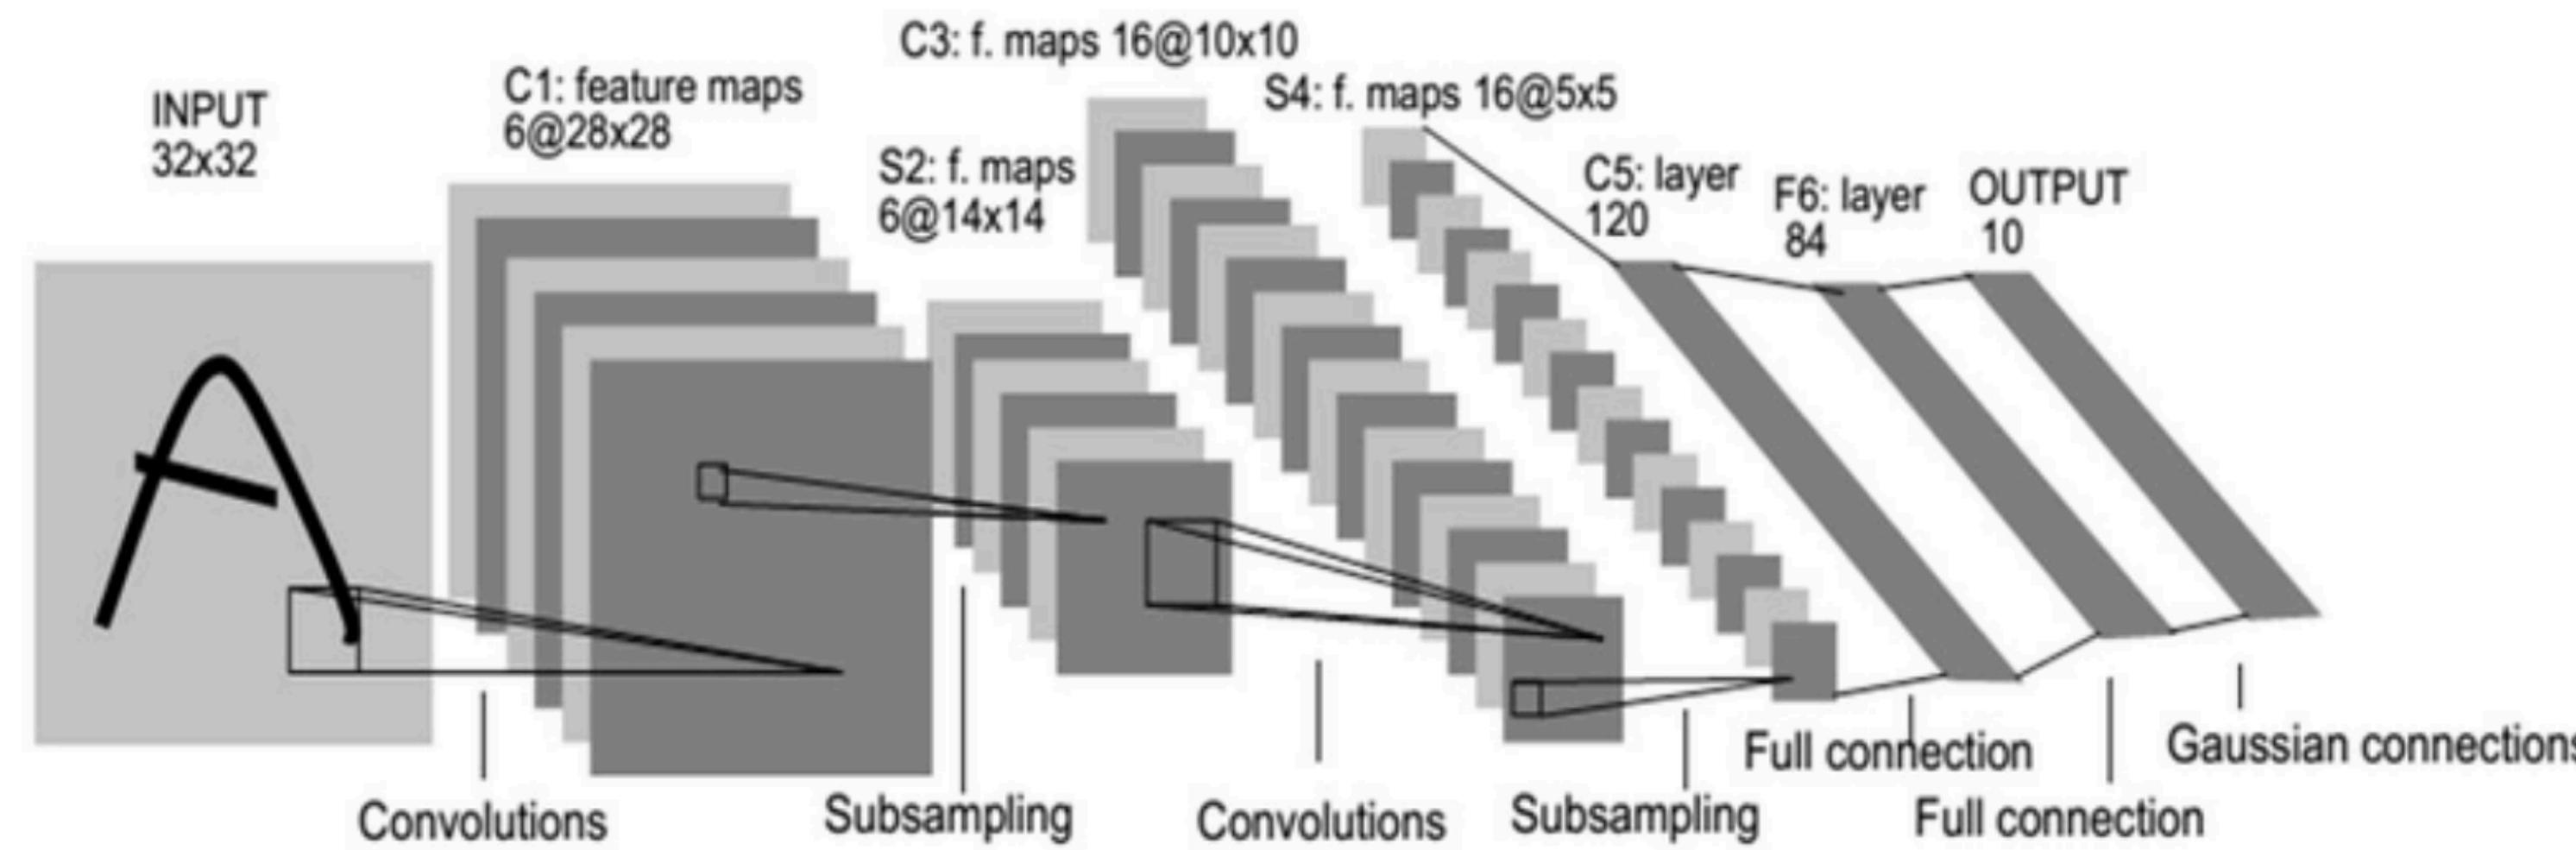

- By **pooling**, we gain robustness to the exact spatial location of features

# Convolutional Neural Network

## Example: LeNet5

- Input:  $32 \times 32$  images (MNIST)
- Convolution 1: 6  $5 \times 5$  filters, stride 1
  - Output: 6  $28 \times 28$  maps
- Pooling 1:  $2 \times 2$  max pooling, stride 2
  - Output: 6  $14 \times 14$  maps
- Convolution 2: 16  $5 \times 5$  filters, stride 1
  - Output: 16  $10 \times 10$  maps
- Pooling 2:  $2 \times 2$  max pooling with stride 2
  - Output: 16  $5 \times 5$  maps (total 400 values)
- 3 fully connected layers: 120  $\Rightarrow$  84  $\Rightarrow$  10 neurons

# Convolutional Neural Network

## Training

- Training:
  - Apply SGD to minimize in-sample training error
  - Backpropagation can be extended to **convolutional layer** and **pooling layer** to compute gradient!
  - Millions of parameters  $\Rightarrow$  easy to overfit

# Convolutional Neural Network

## Revisit Alexnet

- Dropout: 0.5 (in FC layers)
- A lot of data augmentation
- Momentum SGD with batch size 128, momentum factor 0.9
- L2 weight decay (L2 regularization)
- Learning rate: 0.01, decreased by 10 every time when reaching a stable validation accuracy

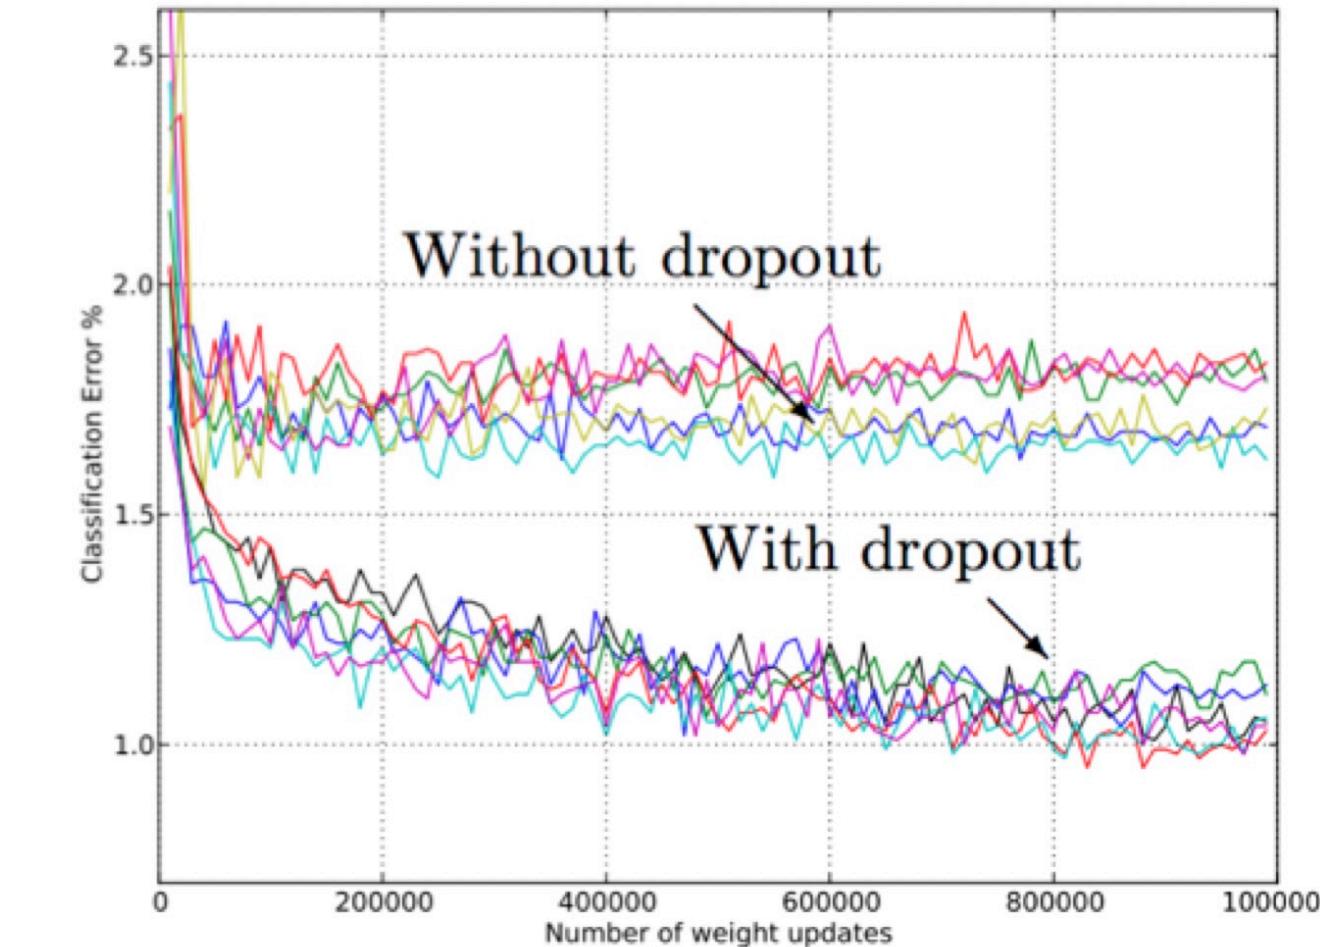

# Convolutional Neural Network

## Dropout

- One of the most effective regularization for deep neural networks

Method	CIFAR-10	CIFAR-100
Conv Net + max pooling (hand tuned)	15.60	43.48
Conv Net + stochastic pooling (Zeiler and Fergus, 2013)	15.13	42.51
Conv Net + max pooling (Snoek et al., 2012)	14.98	-
Conv Net + max pooling + dropout fully connected layers	14.32	41.26
Conv Net + max pooling + dropout in all layers	12.61	<b>37.20</b>
Conv Net + maxout (Goodfellow et al., 2013)	<b>11.68</b>	38.57

Table 4: Error rates on CIFAR-10 and CIFAR-100.

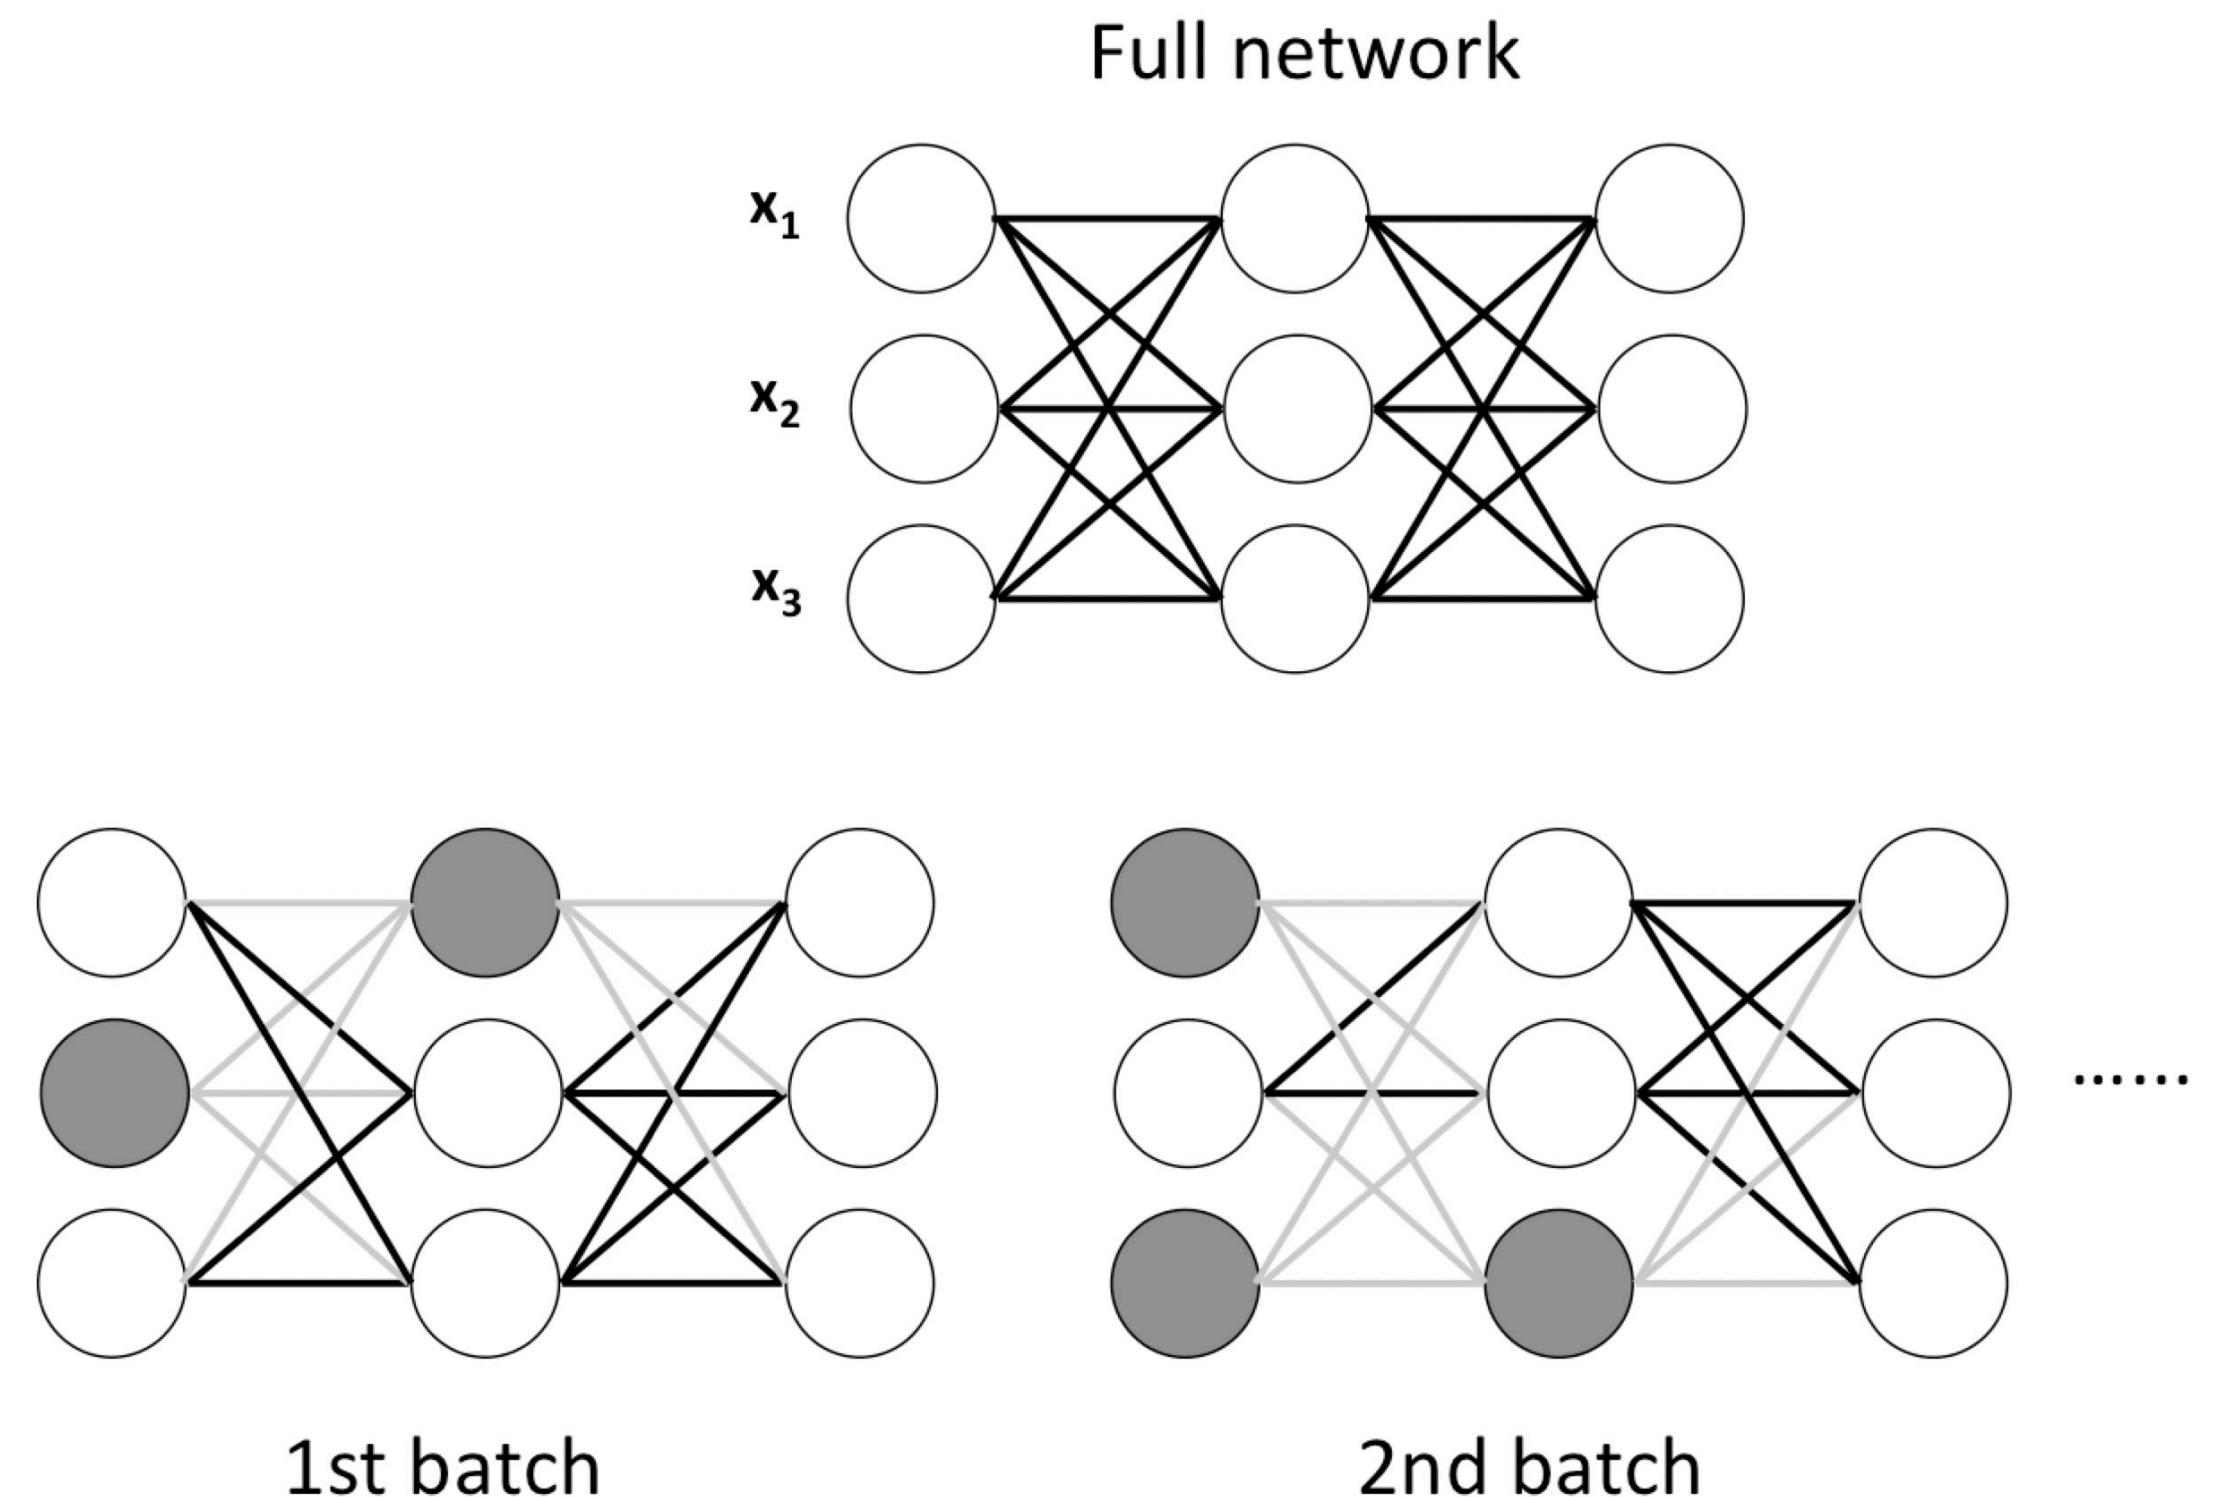

Srivastava et al, "Dropout: A Simple Way to Prevent Neural Networks from Overfitting", 2014.

# Convolutional Neural Network

## Dropout(**training**)

- Dropout in the **training** phase:
  - For each batch, turn off each neuron (including inputs) with a probability  $1 - \alpha$
  - Zero out the removed nodes/edges and do backpropogation

# Convolutional Neural Network

## Dropout(test)

- The model is different from the full model:
- Each neuron computes
  - $x_i^{(l)} = B\sigma(\sum_j W_{ij}^{(l)}x_j^{(l-1)} + b_i^{(l)})$
  - Where B is Bernoulli variable that takes 1 with probability  $\alpha$
- The expected output of the neuron:
  - $E[x_i^{(l)}] = \alpha\sigma(\sum_j W_{ij}^{(l)}x_j^{(l-1)} + b_i^{(l)})$
- Use the **expected output** at test time  $\Rightarrow$  multiply all the weights by  $\alpha$

# Convolutional Neural Network

## Batch Normalization

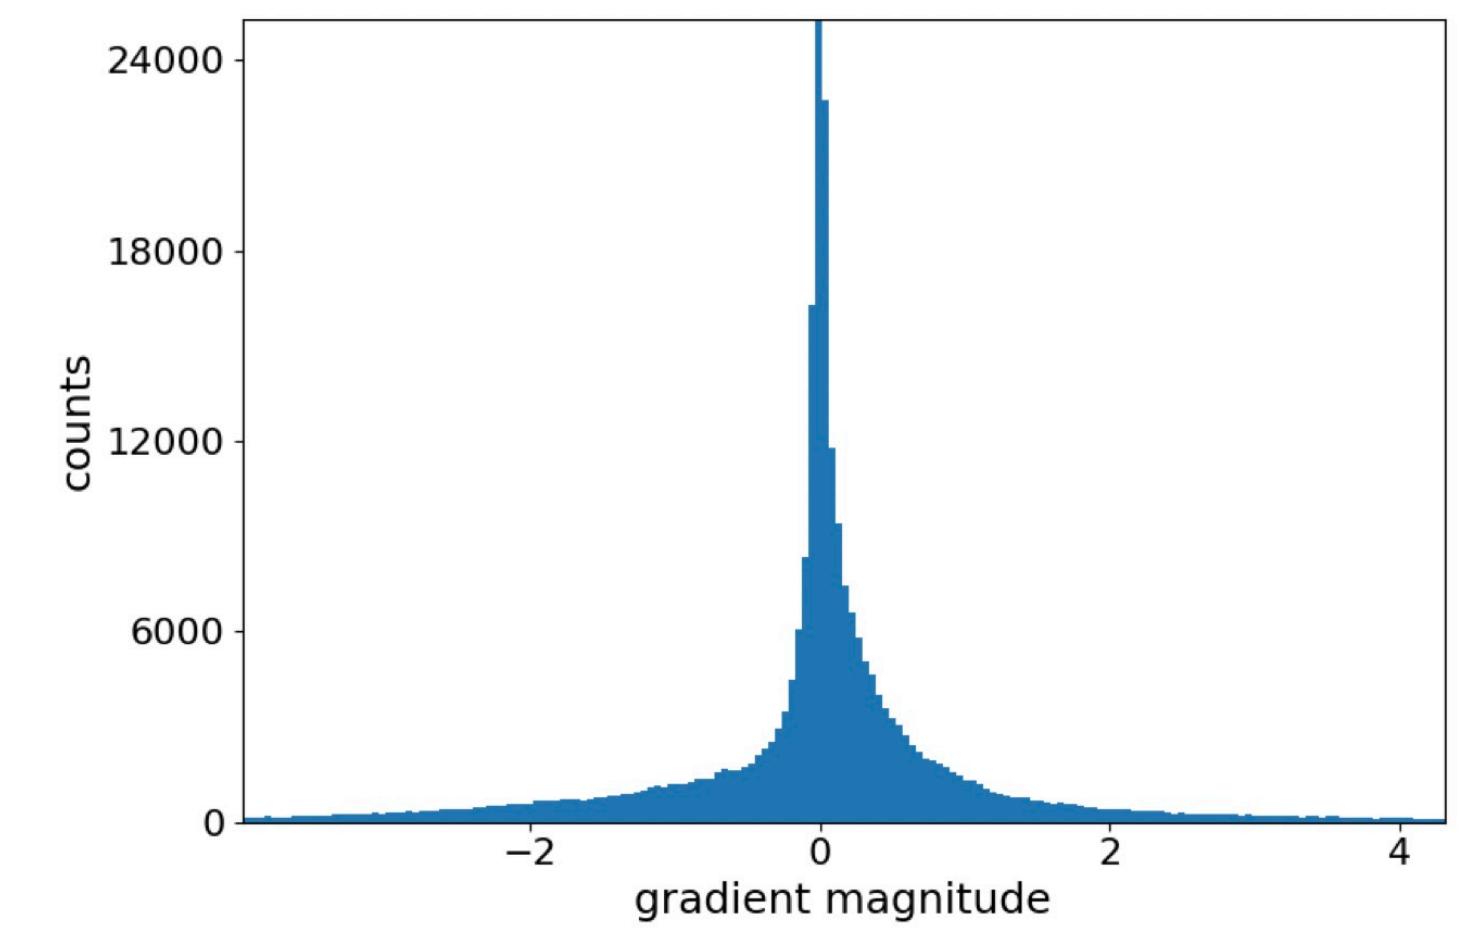

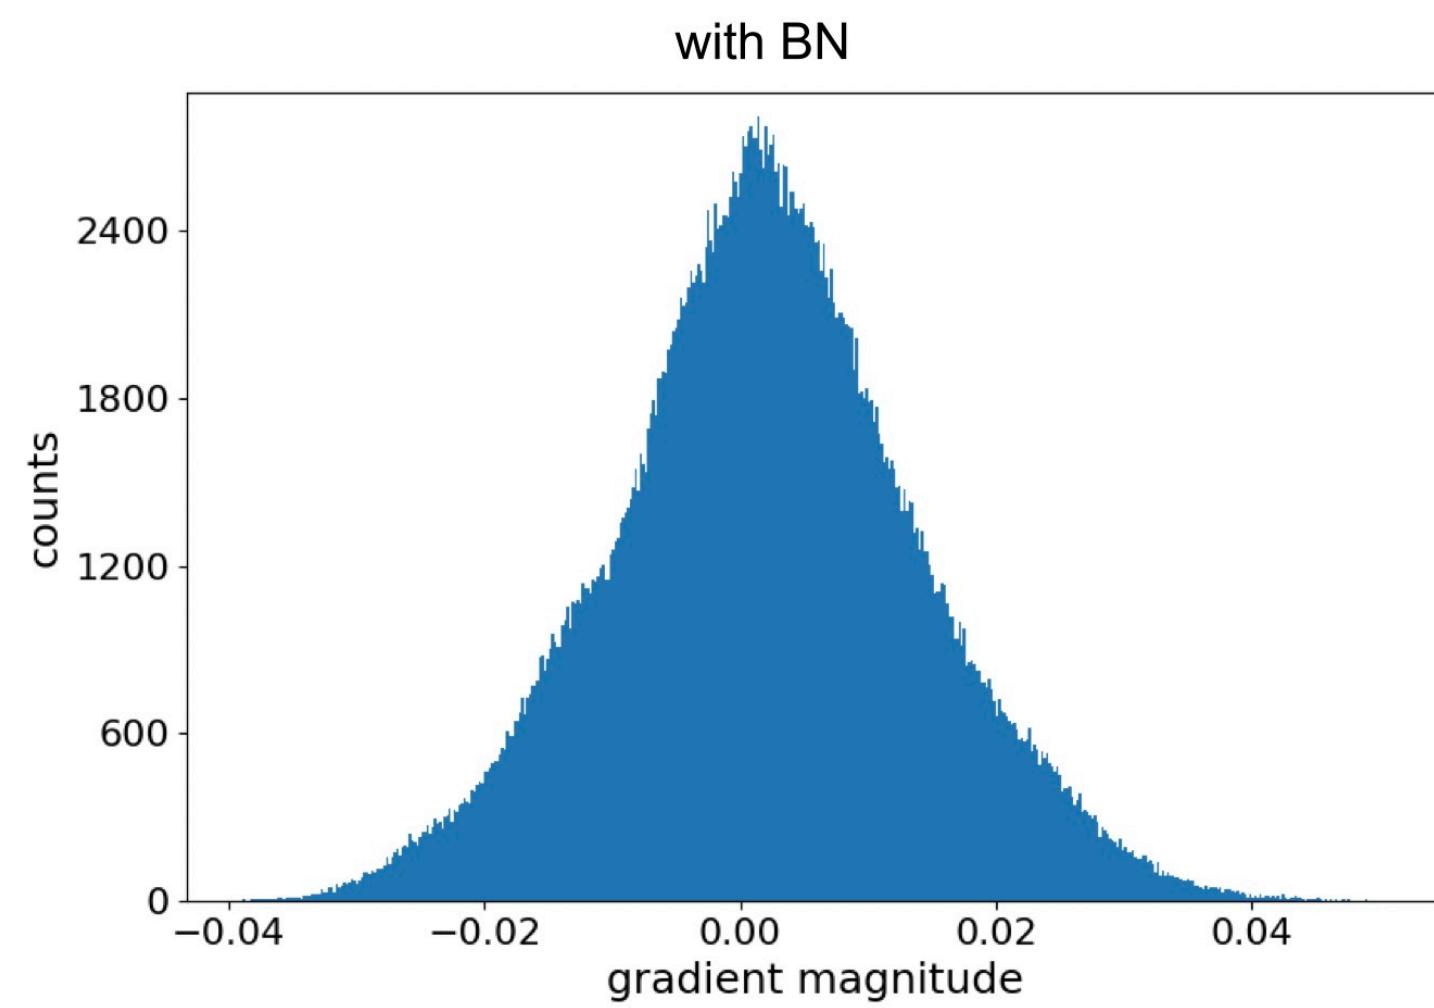

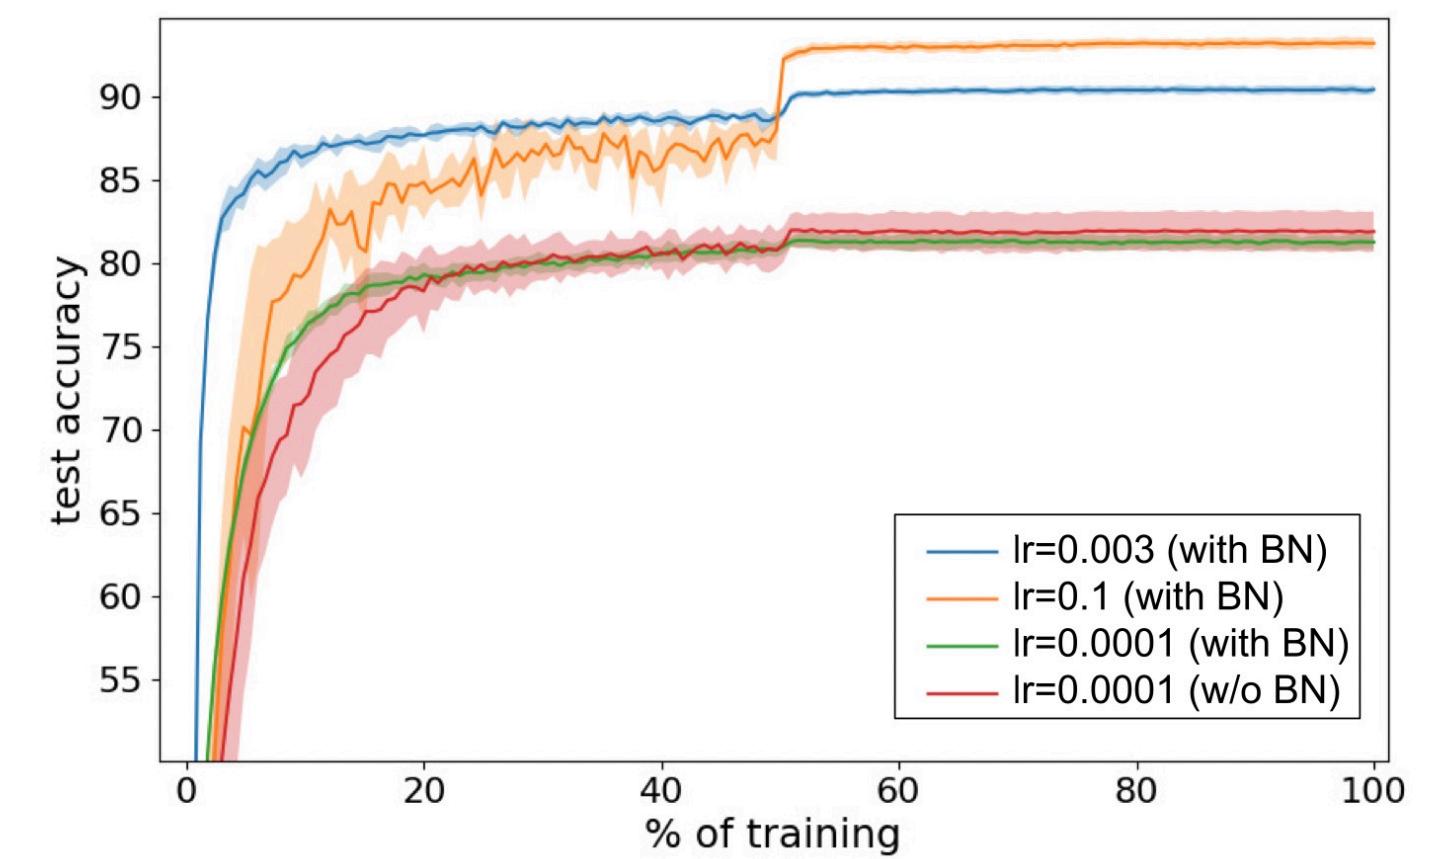

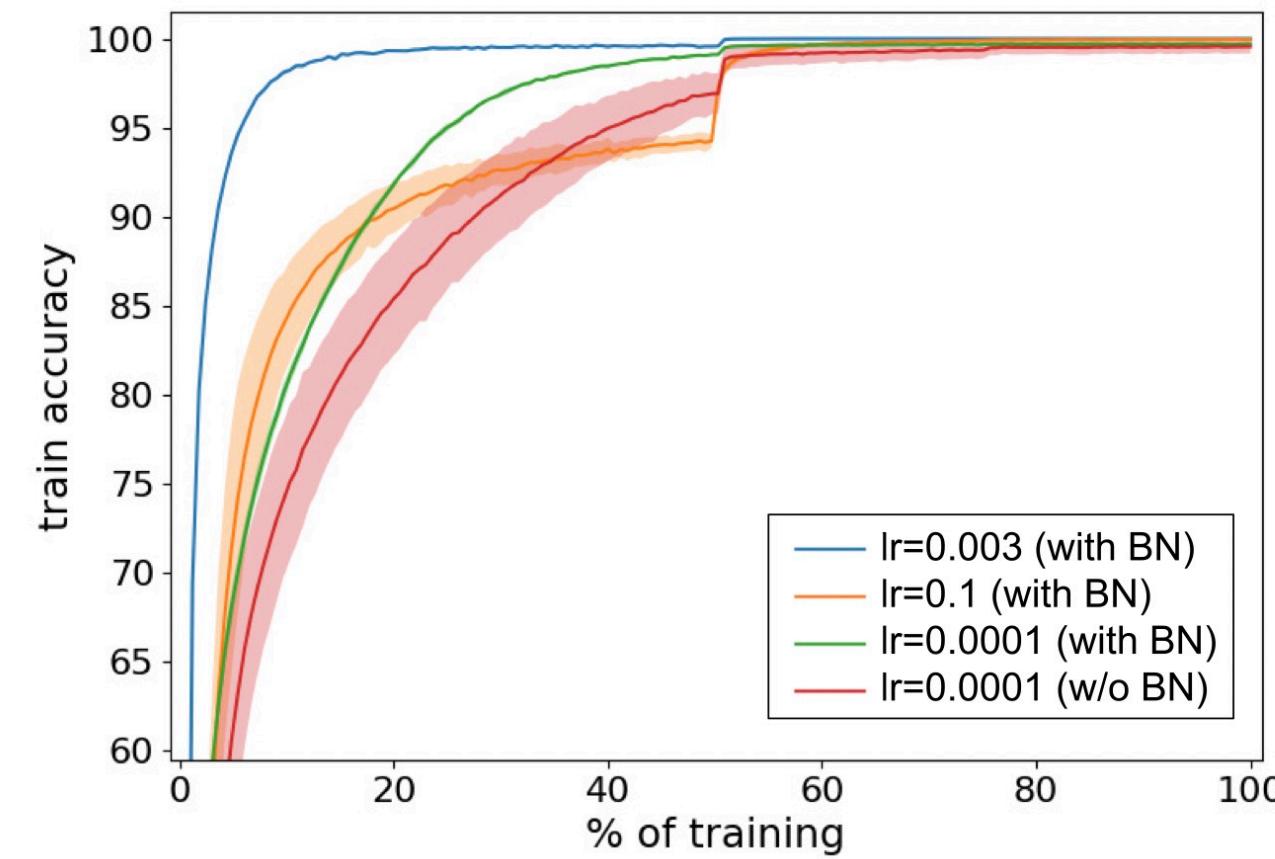

- Initially proposed to reduce co-variate shift

- $$O_{b,c,x,y} \leftarrow \gamma \frac{I_{b,c,x,y} - \mu_c}{\sqrt{\sigma_c^2 + \epsilon}} + \beta \quad \forall b, c, x, y,$$
- $\mu_c = \frac{1}{|B|} \sum_{b,x,y} I_{b,c,x,y}$ : the mean for channel  $c$ , and  $\sigma_c$  standard deviation.
- $\gamma$  and  $\beta$ : two learnable parameters

# Convolutional Neural Network

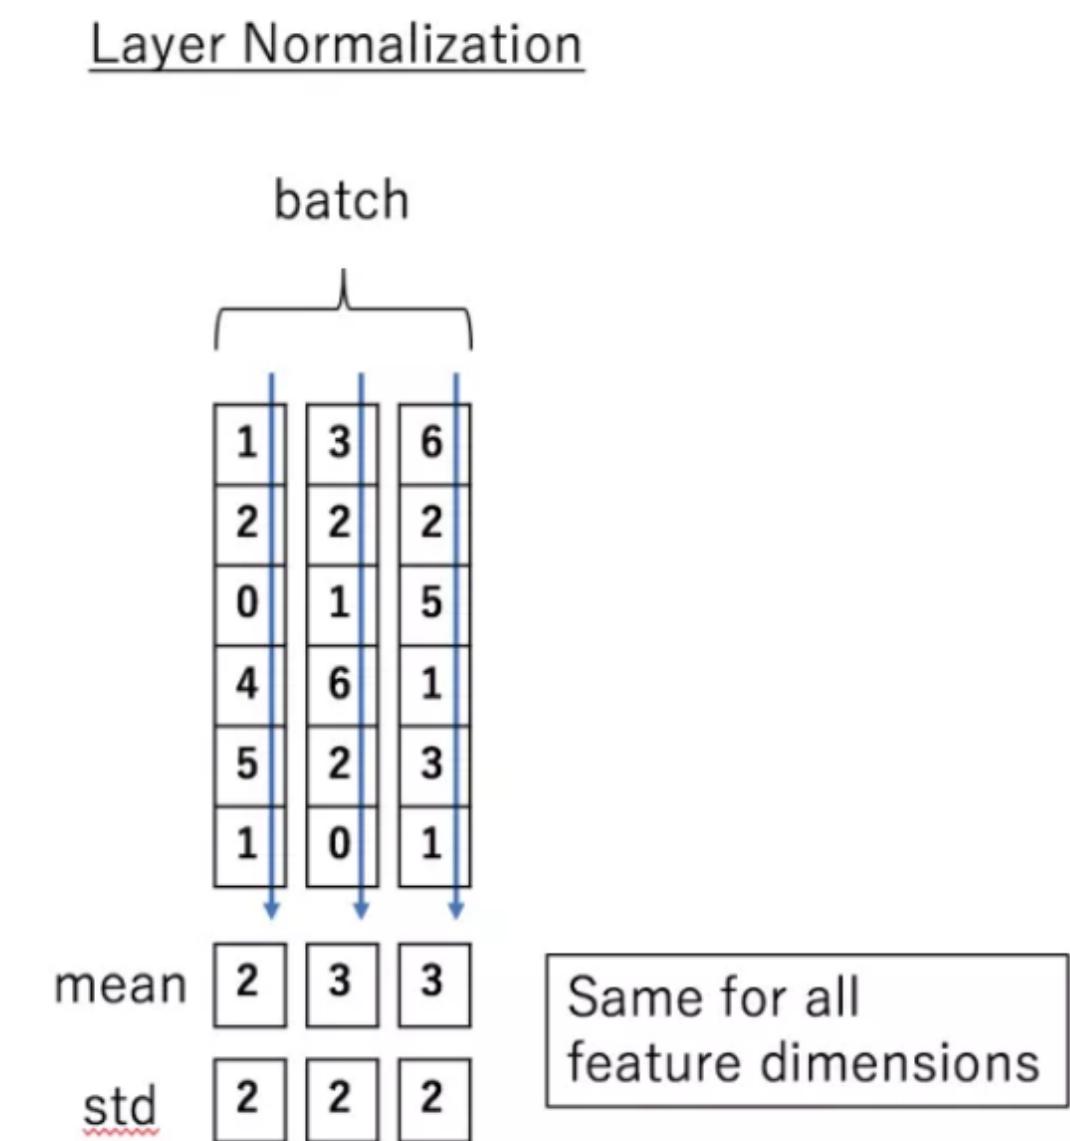

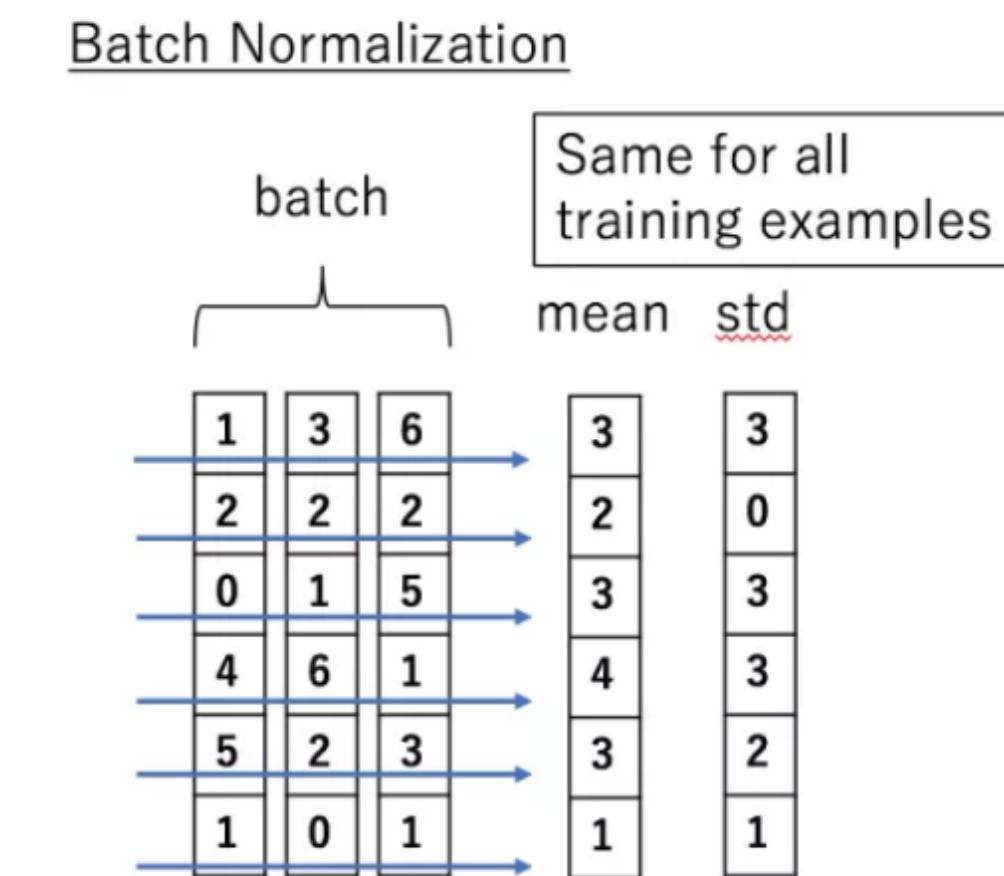

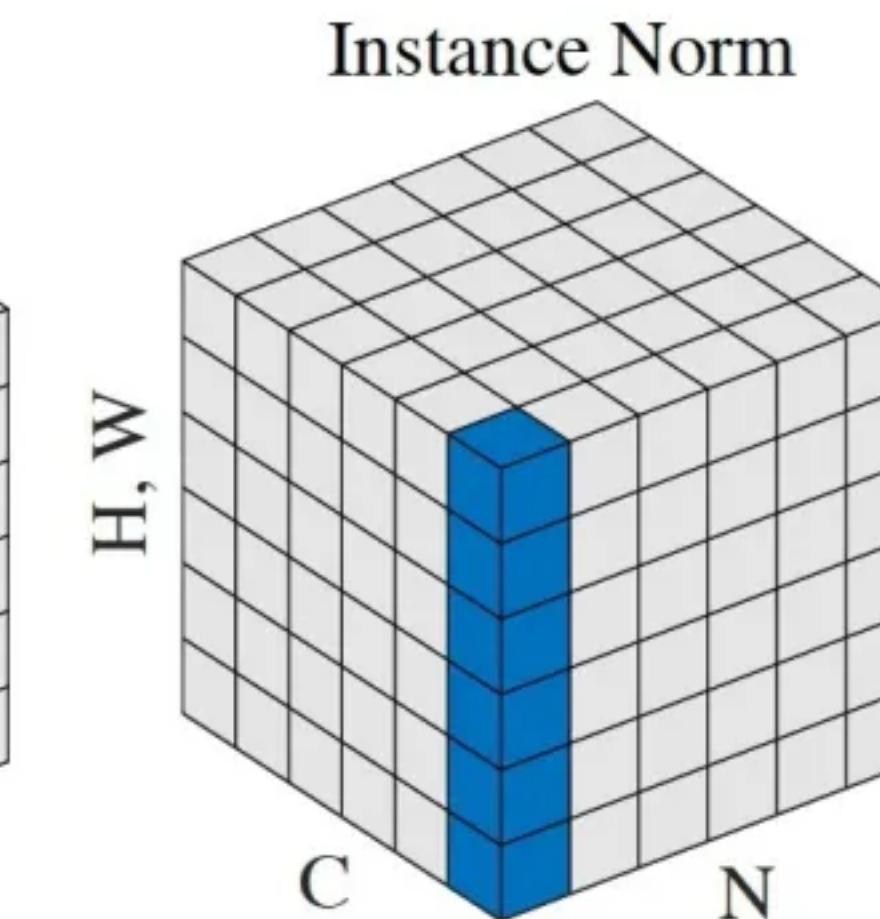

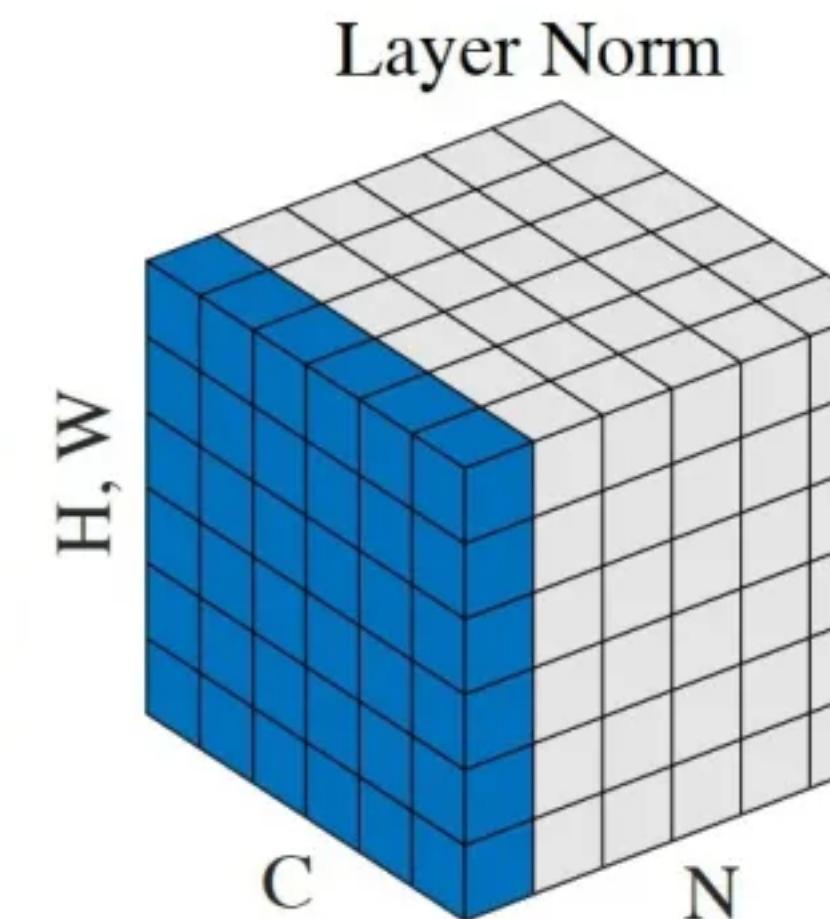

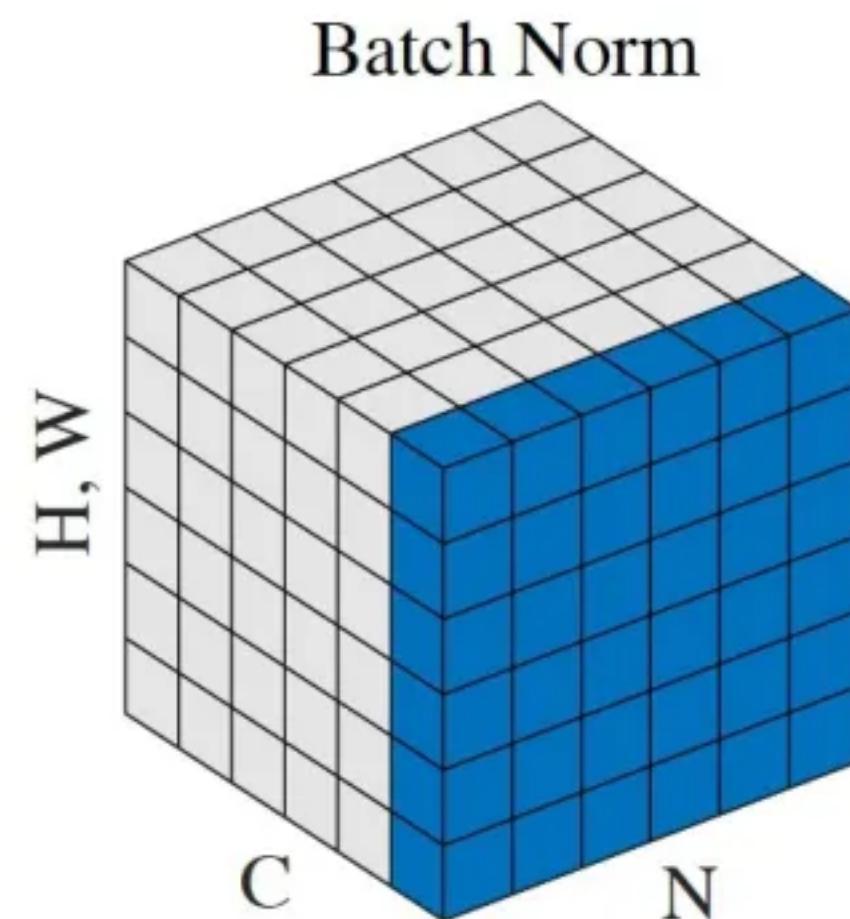

## Batch Normalization

- Couldn't reduce covariate shift (Ilyas et al 2018)
- Allow larger learning rate
  - Constraint the gradient norm

# Convolutional Neural Network

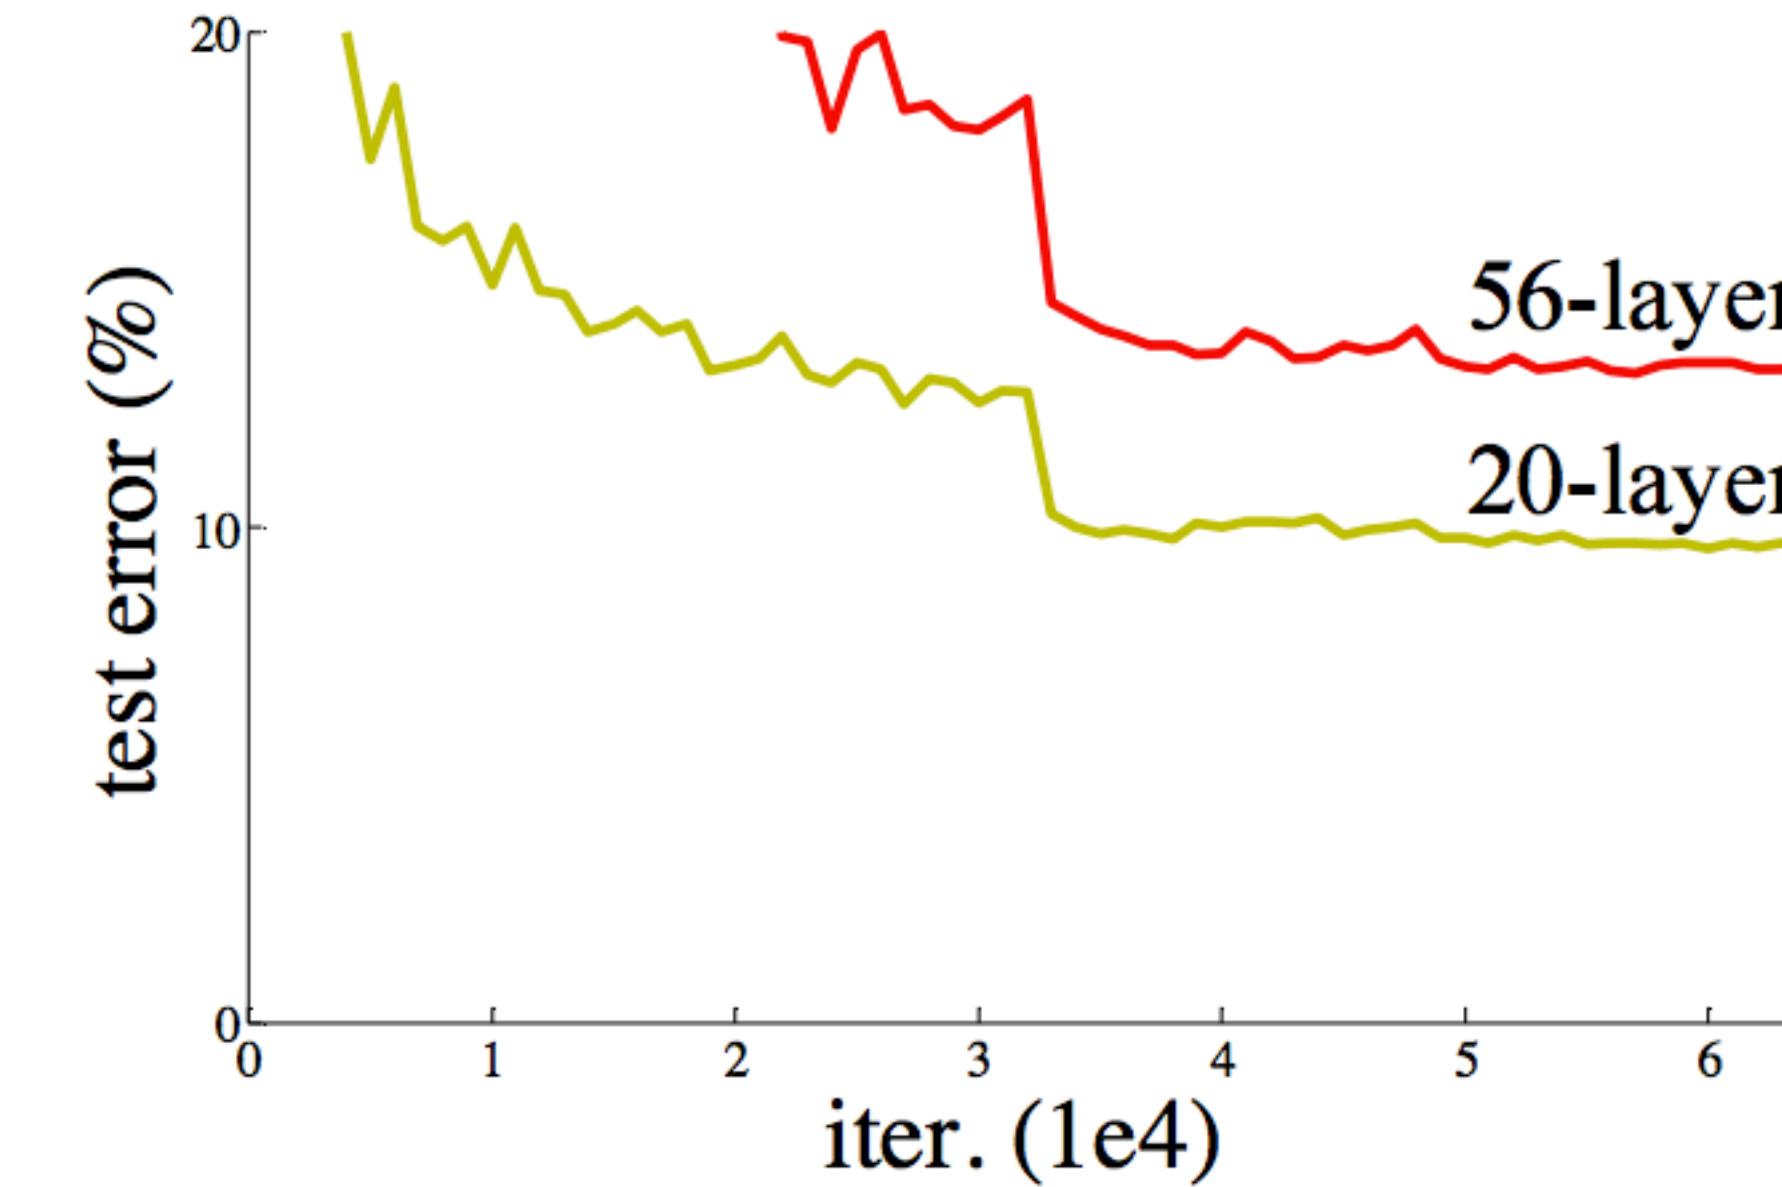

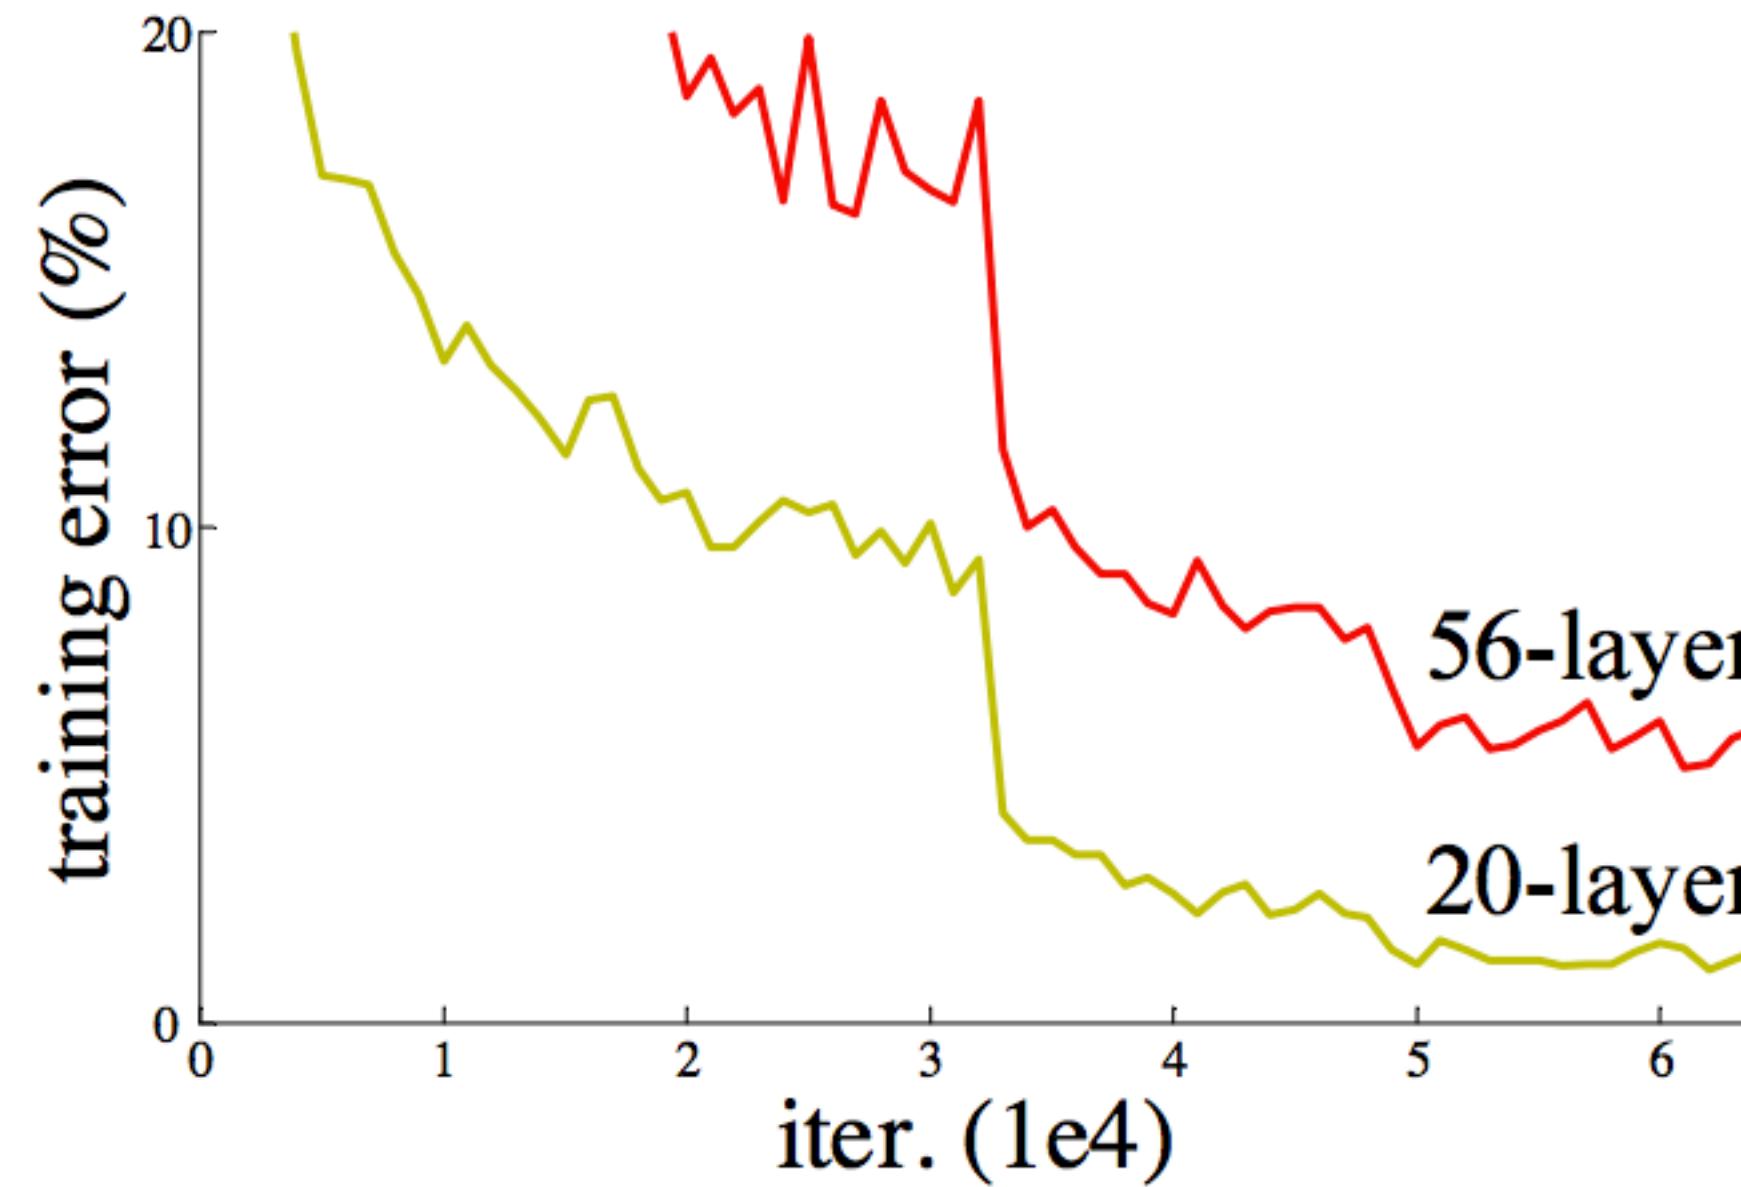

## Other normalization

# Convolutional Neural Network

## Residual Networks

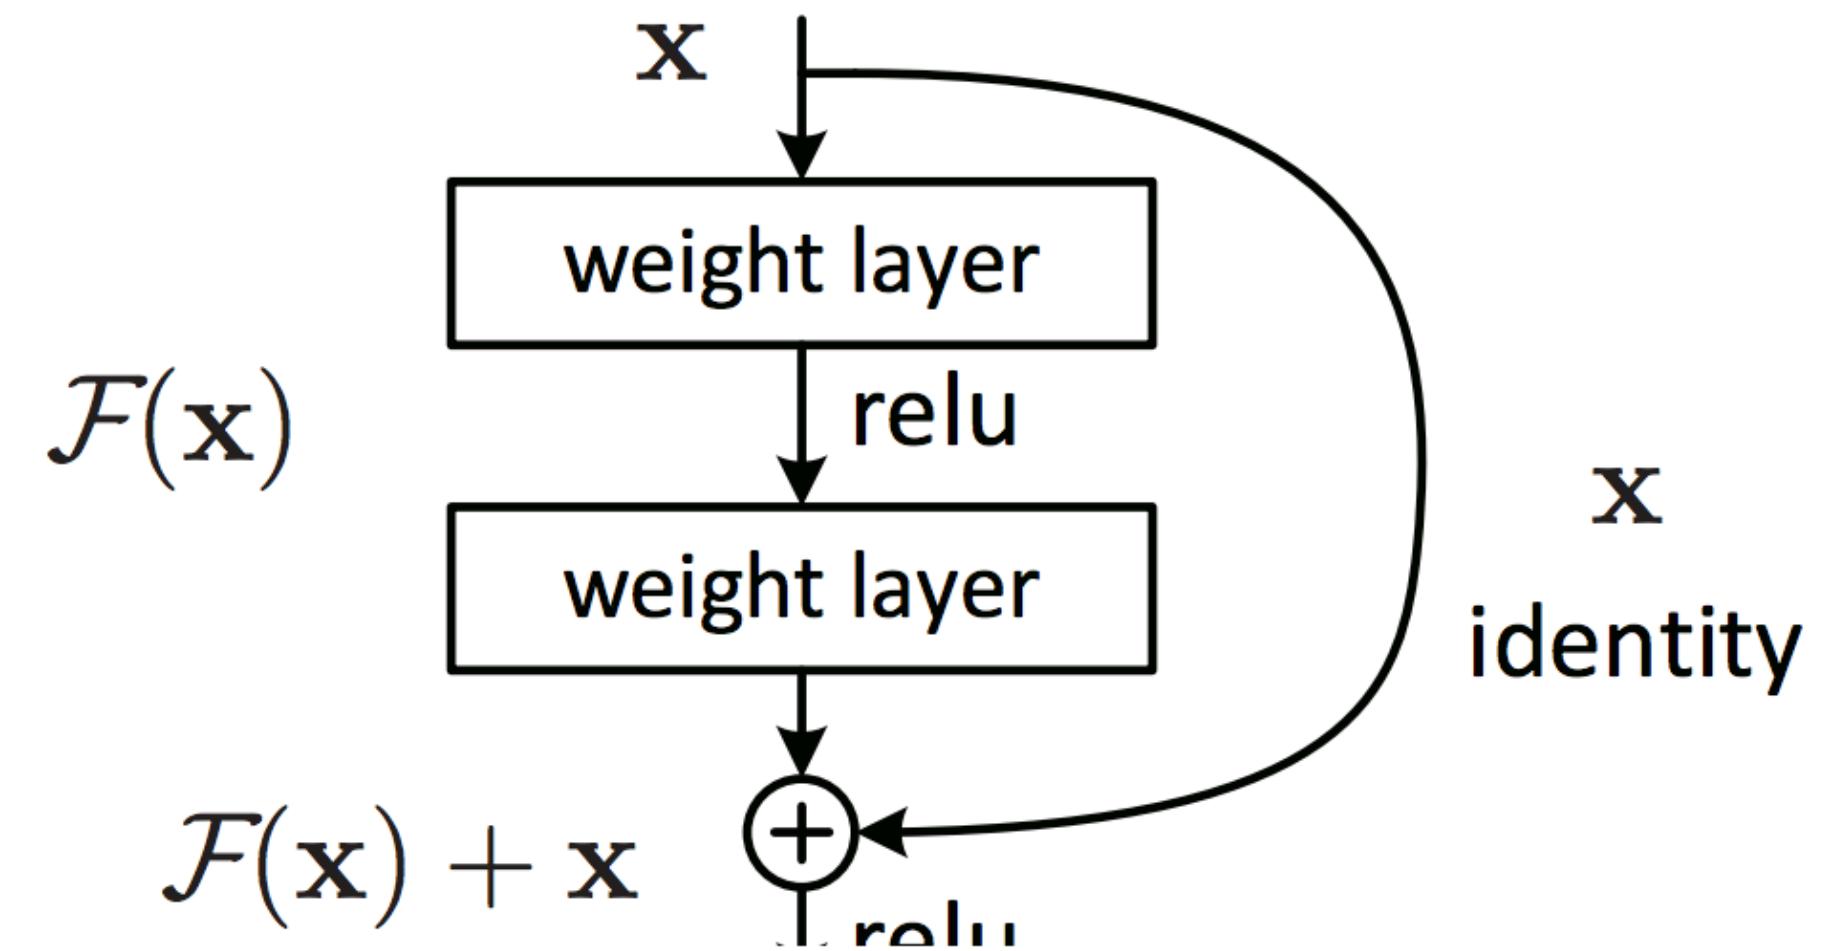

- Very deep convnets do not train well – **vanishing gradient problem**

# Convolutional Neural Network

## Residual Networks

- Key idea: introduce “pass through” into each layer

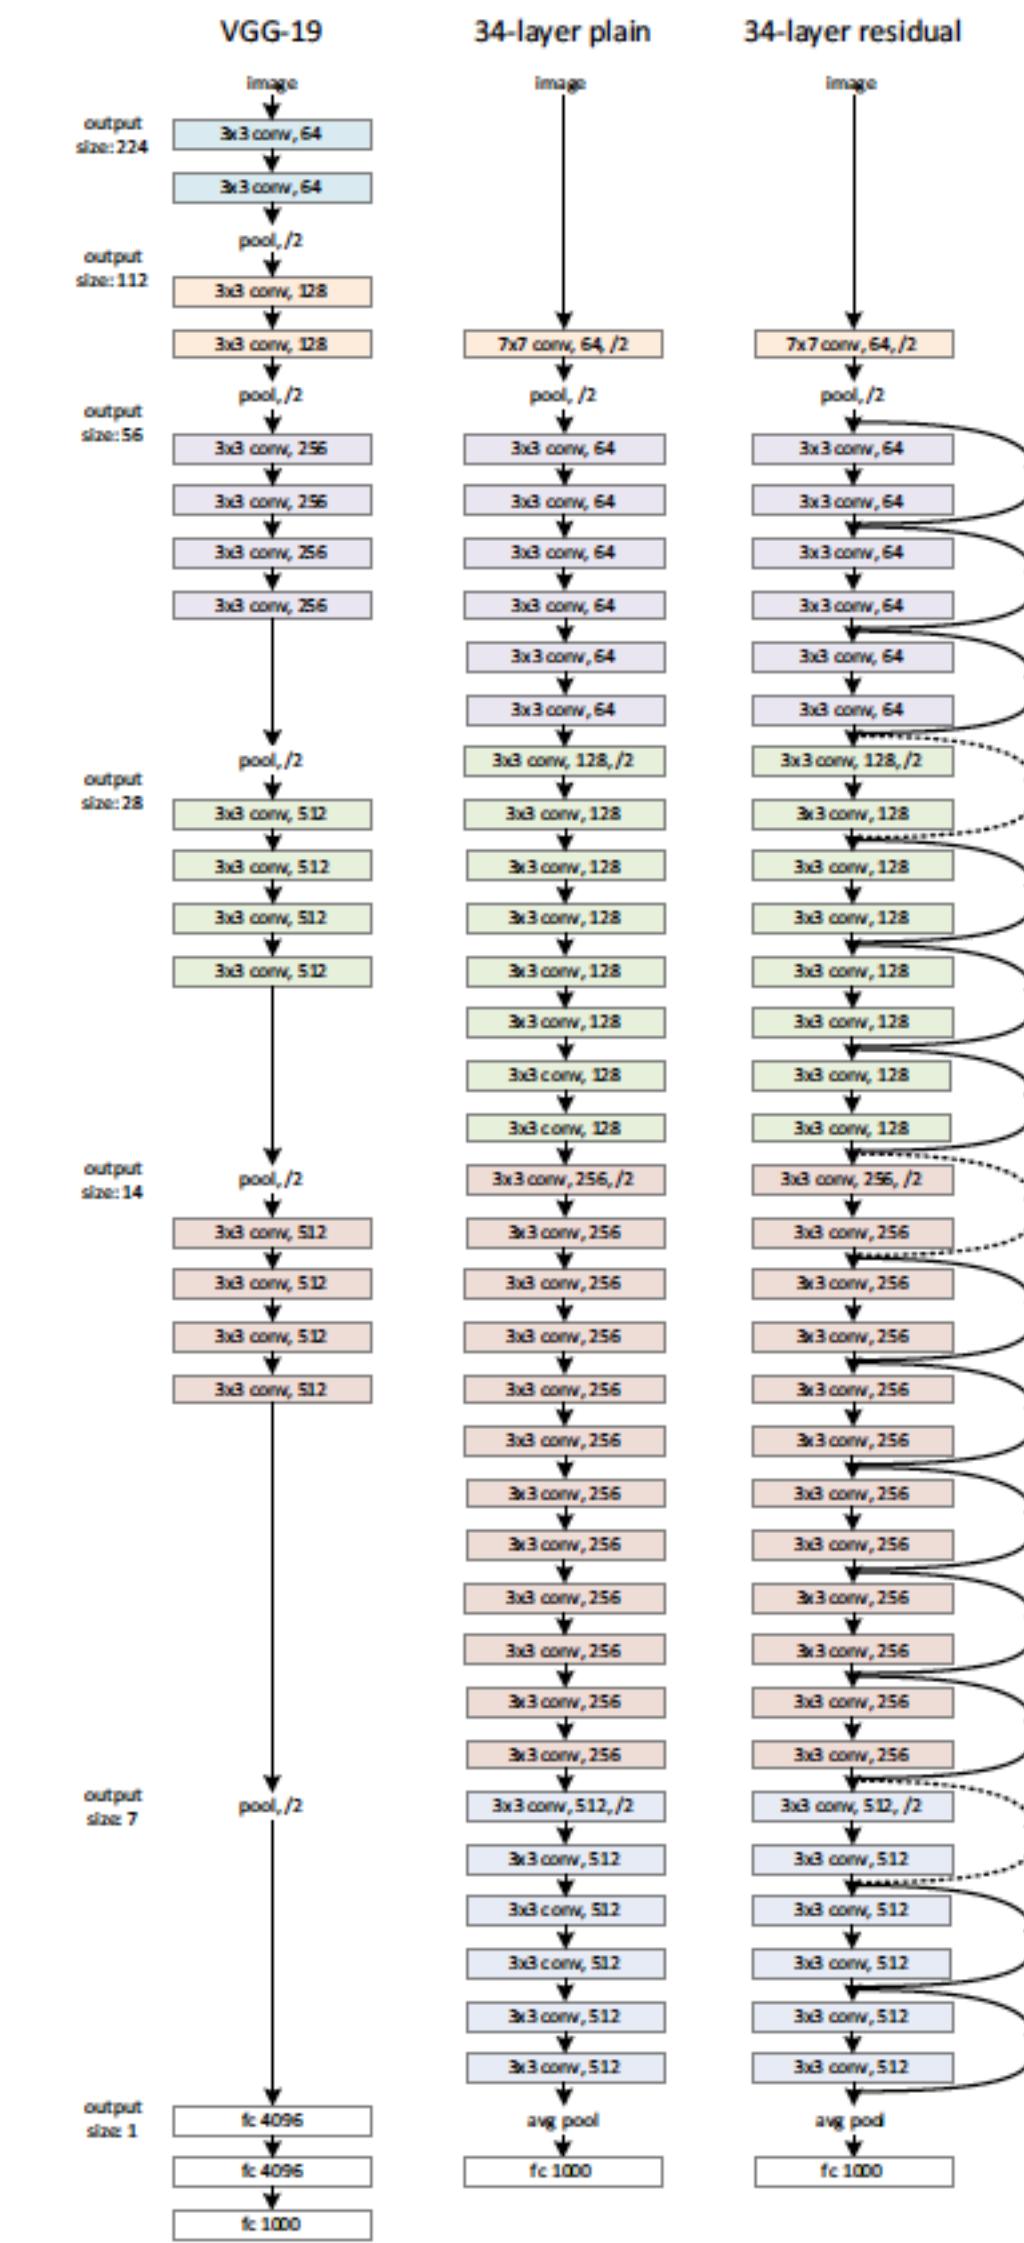

- Thus, only residual needs to be learned

# Convolutional Neural Network Residual Networks

# Representation for sentence/document

## Bag of word

- A classical way to represent NLP data
- Each sentence (or document) is represented by a  $d$ -dimensional vector  $\mathbf{x}$ , where  $x_i$  is number of occurrences of word  $i$
- number of features = number of potential words (very large)

# Representation for sentence/document

## Feature generation for documents

- Bag of  $n$ -gram features ( $n = 2$ ):
  - 10,000 words  $\Rightarrow 10000^2$  potential features

# Representation for sentence/document

## Bag of word + linear model

- Example: text classification (e.g., sentiment prediction, review score prediction)
- Linear model:  $y \approx \text{sign}(w^T x)$  (e.g., by linear SVM/logistic regression)
- $w_i$ : the “contribution” of each word

# Representation for sentence/document

## Bag of word + Fully connected network

- $f(x) = W_L \sigma(W_{L-1} \cdots \sigma(W_0 x))$
- The first layer  $W_0$  is a  $d_1$  by  $d$  matrix:
  - Each column  $w_i$  is a  $d_1$  dimensional representation of  $i$ -th word (word embedding)
  - $W_0 x = x_1 w_1 + x_2 w_2 + \cdots + x_d w_d$  is a linear combination of these vectors
  - $W_0$  is also called the word embedding matrix
  - Final prediction can be viewed as an  $L - 1$  layer network on  $W_0 x$  (average of word embeddings)
- Not capturing the sequential information

# Recurrent Neural Network

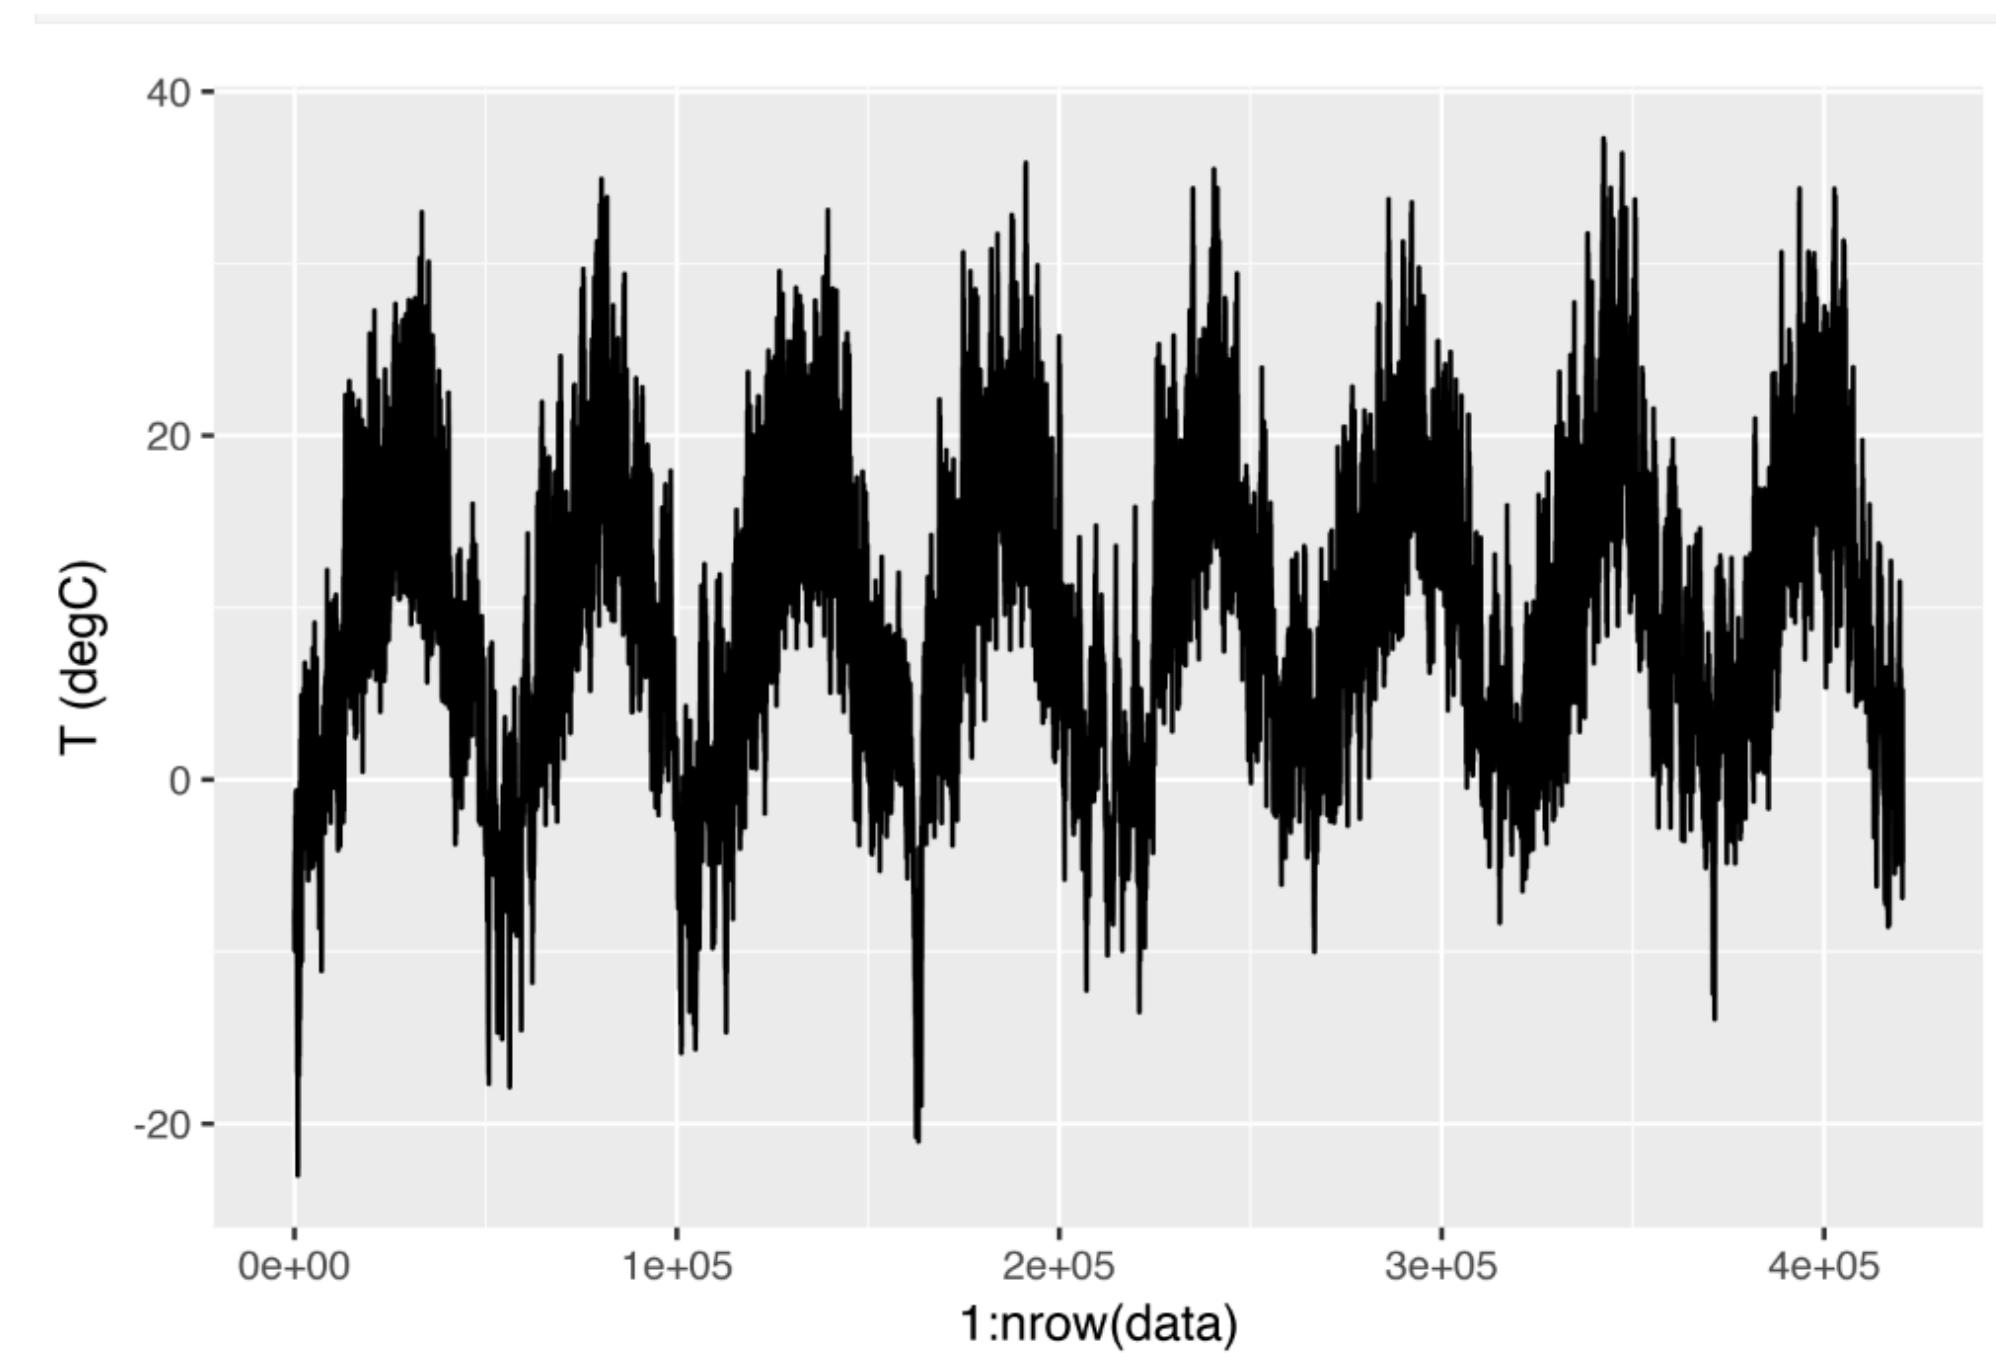

## Time series/Sequence data

- Input:  $\{x_1, x_2, \dots, x_T\}$ 
  - Each  $x_t$  is the feature at time step  $t$
  - Each  $x_t$  can be a  $d$ -dimensional vector
- Output:  $\{y_1, y_2, \dots, y_T\}$ 
  - Each  $y_t$  is the output at step  $t$
  - Multi-class output or Regression output:
    - $y_t \in \{1, 2, \dots, L\}$  or  $y_t \in \mathbb{R}$

# Recurrent Neural Network

## Example: Time Series Prediction

- Climate Data:
  - $x_t$ : temperature at time  $t$
  - $y_t$ : temperature (or temperature change) at time  $t + 1$
- Stock Price: Predicting stock price

# Recurrent Neural Network

## Example: Language Modeling

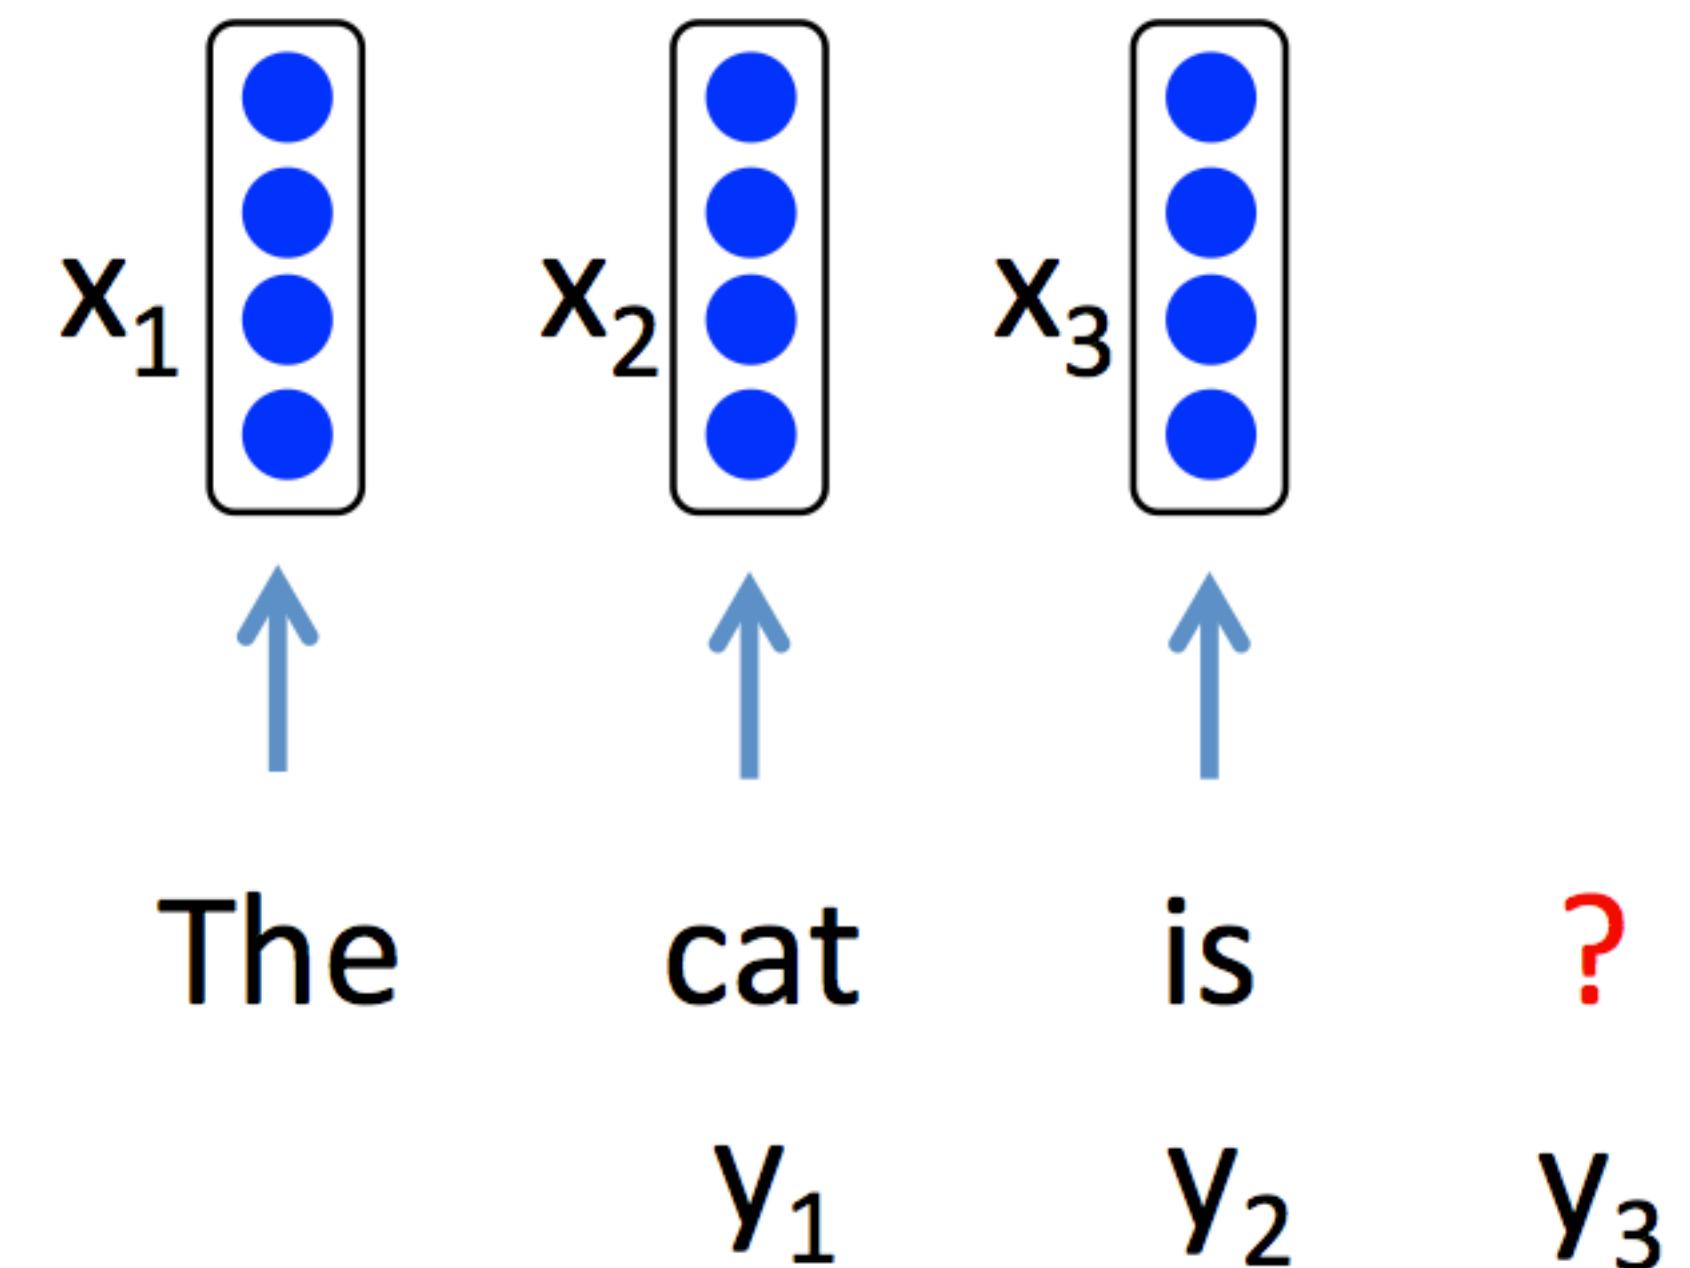

The cat is ?

# Recurrent Neural Network

## Example: Language Modeling

The cat is ?

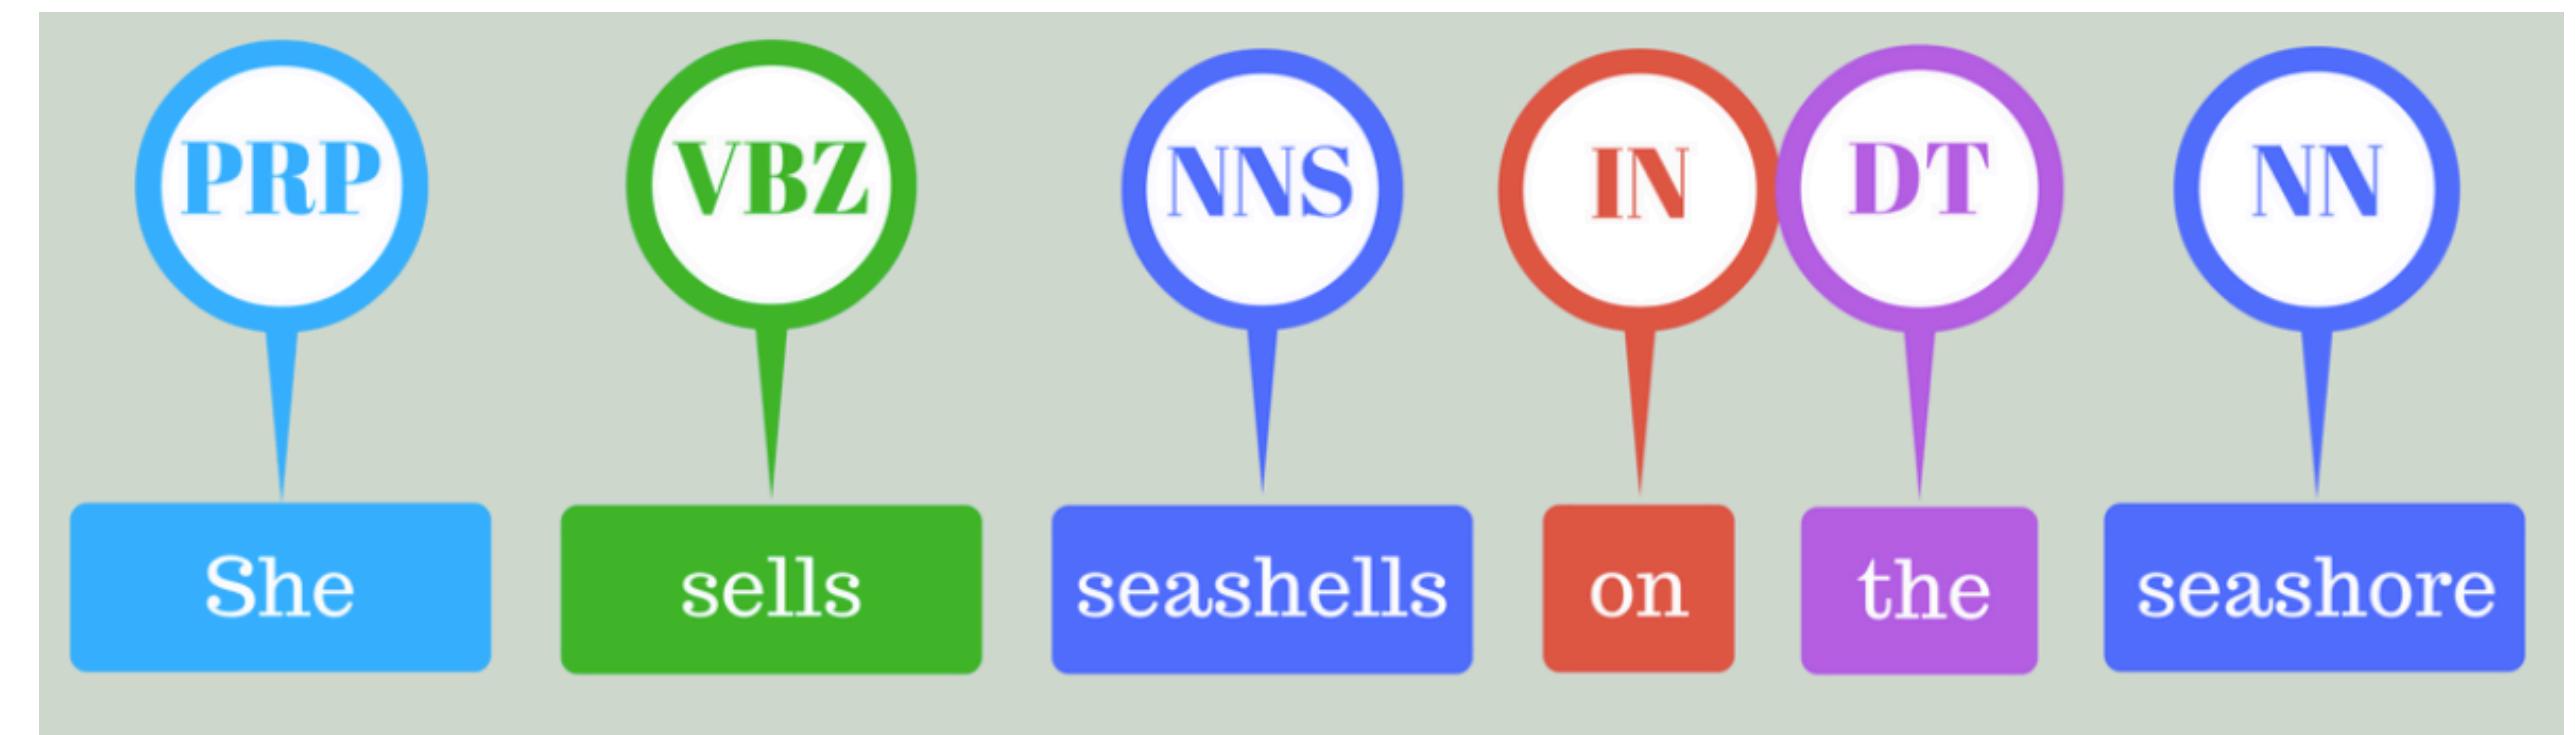

- $x_t$ : one-hot encoding to represent the word at step  $t$  ( $[0, \dots, 0, 1, 0, \dots, 0]$ )
- $y_t$ : the next word
  - $y_t \in \{1, \dots, V\}$   $V$ : Vocabulary size

# Recurrent Neural Network

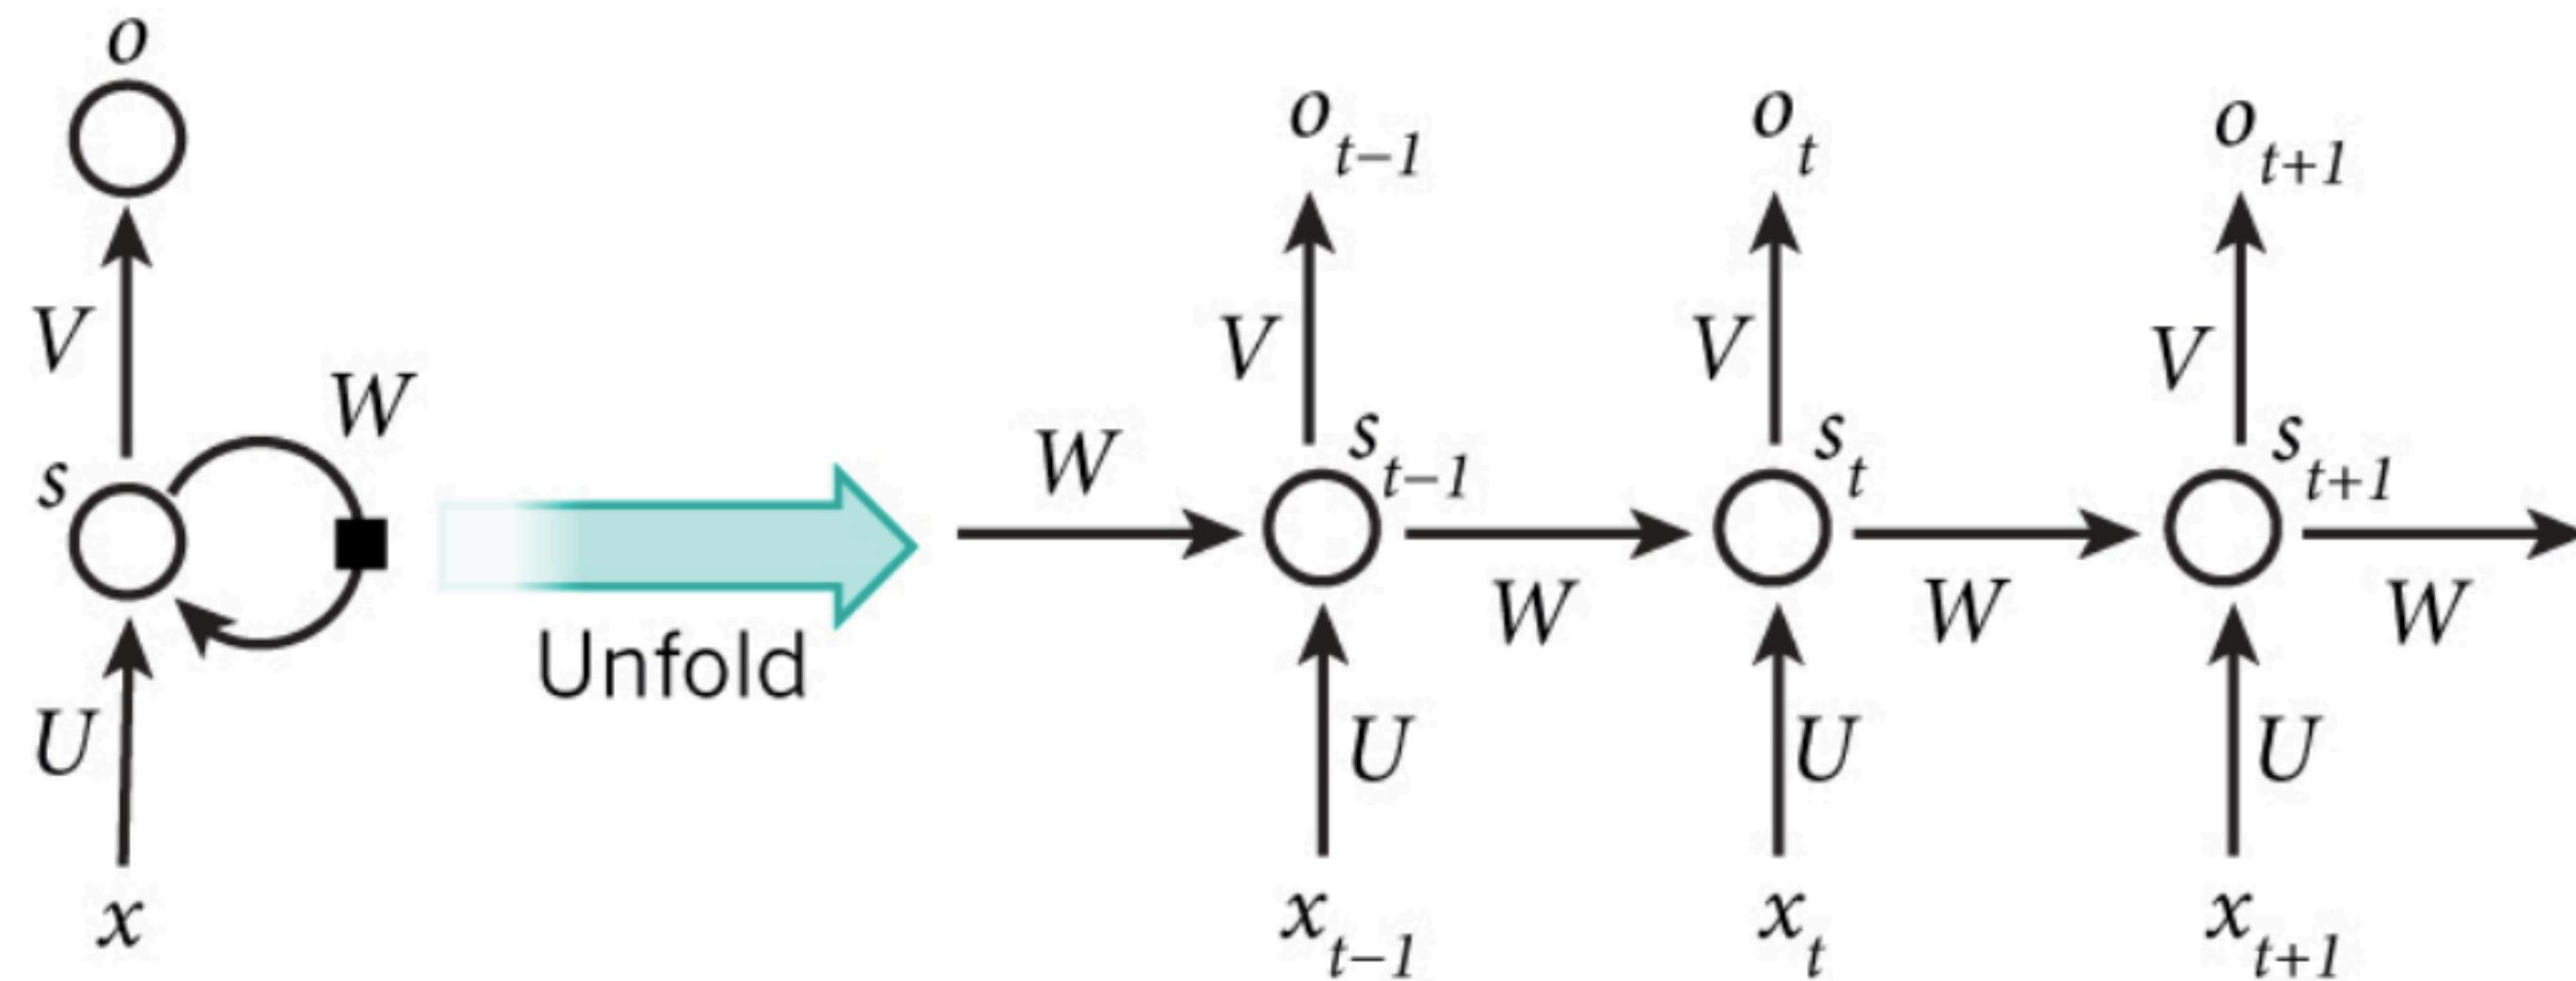

## Example: POS Tagging

- Part of Speech Tagging:
  - Labeling words with their Part-Of-Speech (Noun, Verb, Adjective, ...)
  - $x_t$ : a **vector** to represent the word at step  $t$
  - $y_t$ : label of word  $t$

# Recurrent Neural Network

## Example: POS Tagging

- $x_t$ :  $t$ -th input
- $s_t$ : hidden state at time  $t$  ("memory" of the network)
  - $s_t = f(Ux_t + Ws_{t-1})$
  - $W$ : transition matrix,  $U$ : word embedding matrix,  $s_0$  usually set to be 0
- Predicted output at time  $t$ :
  - $o_t = \arg \max_i (Vs_t)_i$

# Recurrent Neural Network

## Recurrent Neural Network (RNN)

- Training: Find  $U, W, V$  to minimize empirical loss:
- Loss of a sequence:

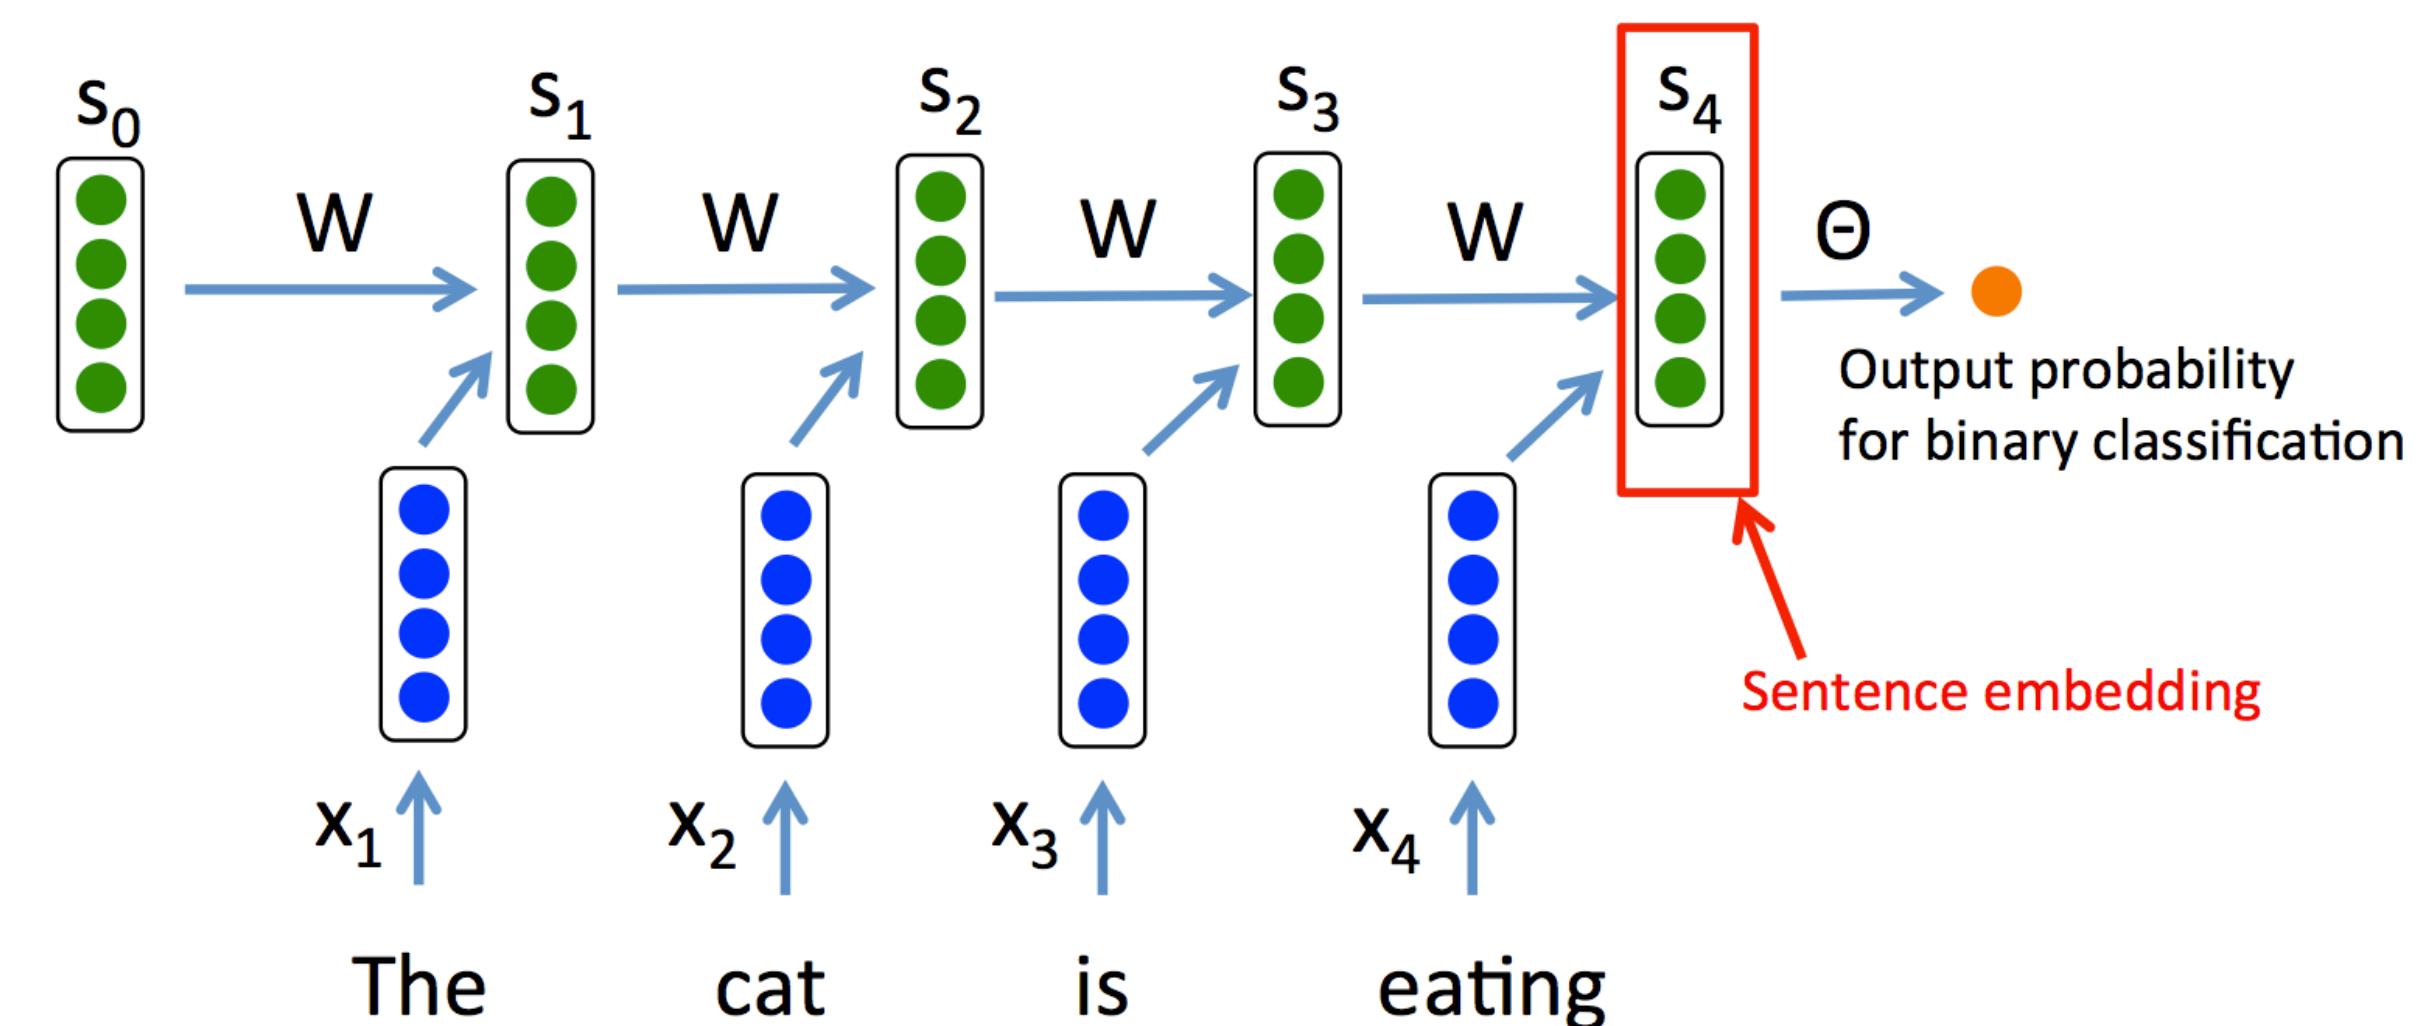

- $$\sum_{t=1}^T \text{loss}(Vs_t, y_t)$$

- ( $s_t$  is a function of  $U, W, V$ )
- Loss on the whole dataset:
  - Average loss over all sequences
  - Solved by SGD/Adam

# Recurrent Neural Network

## RNN: Text Classification

- Not necessary to output at each step
- Text Classification:
  - sentence → category
  - Output only at the final step
- Model: add a fully connected network to the final embedding

# Recurrent Neural Network

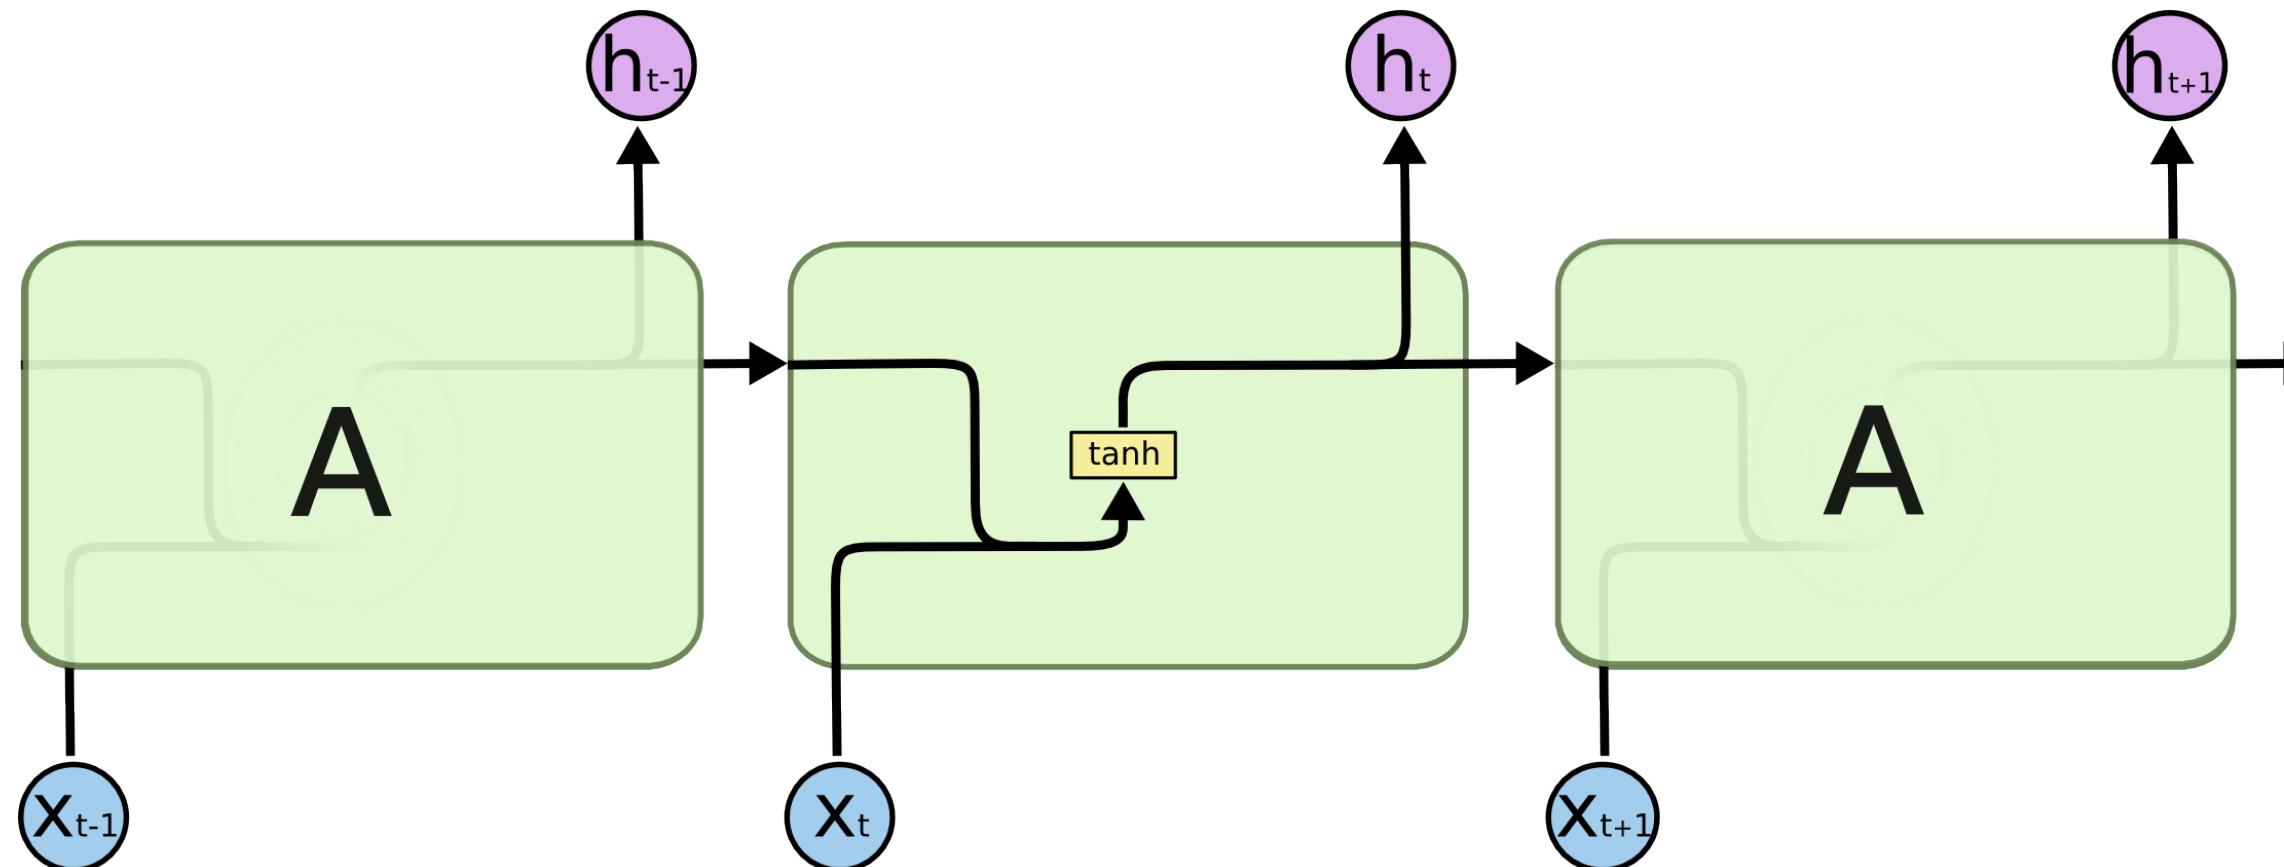

## Problems of Classical RNN

- Hard to capture long-term dependencies
- Hard to solve (vanishing gradient problem)
- Solution:
  - LSTM (Long Short Term Memory networks)
  - GRU (Gated Recurrent Unit)
  - ...

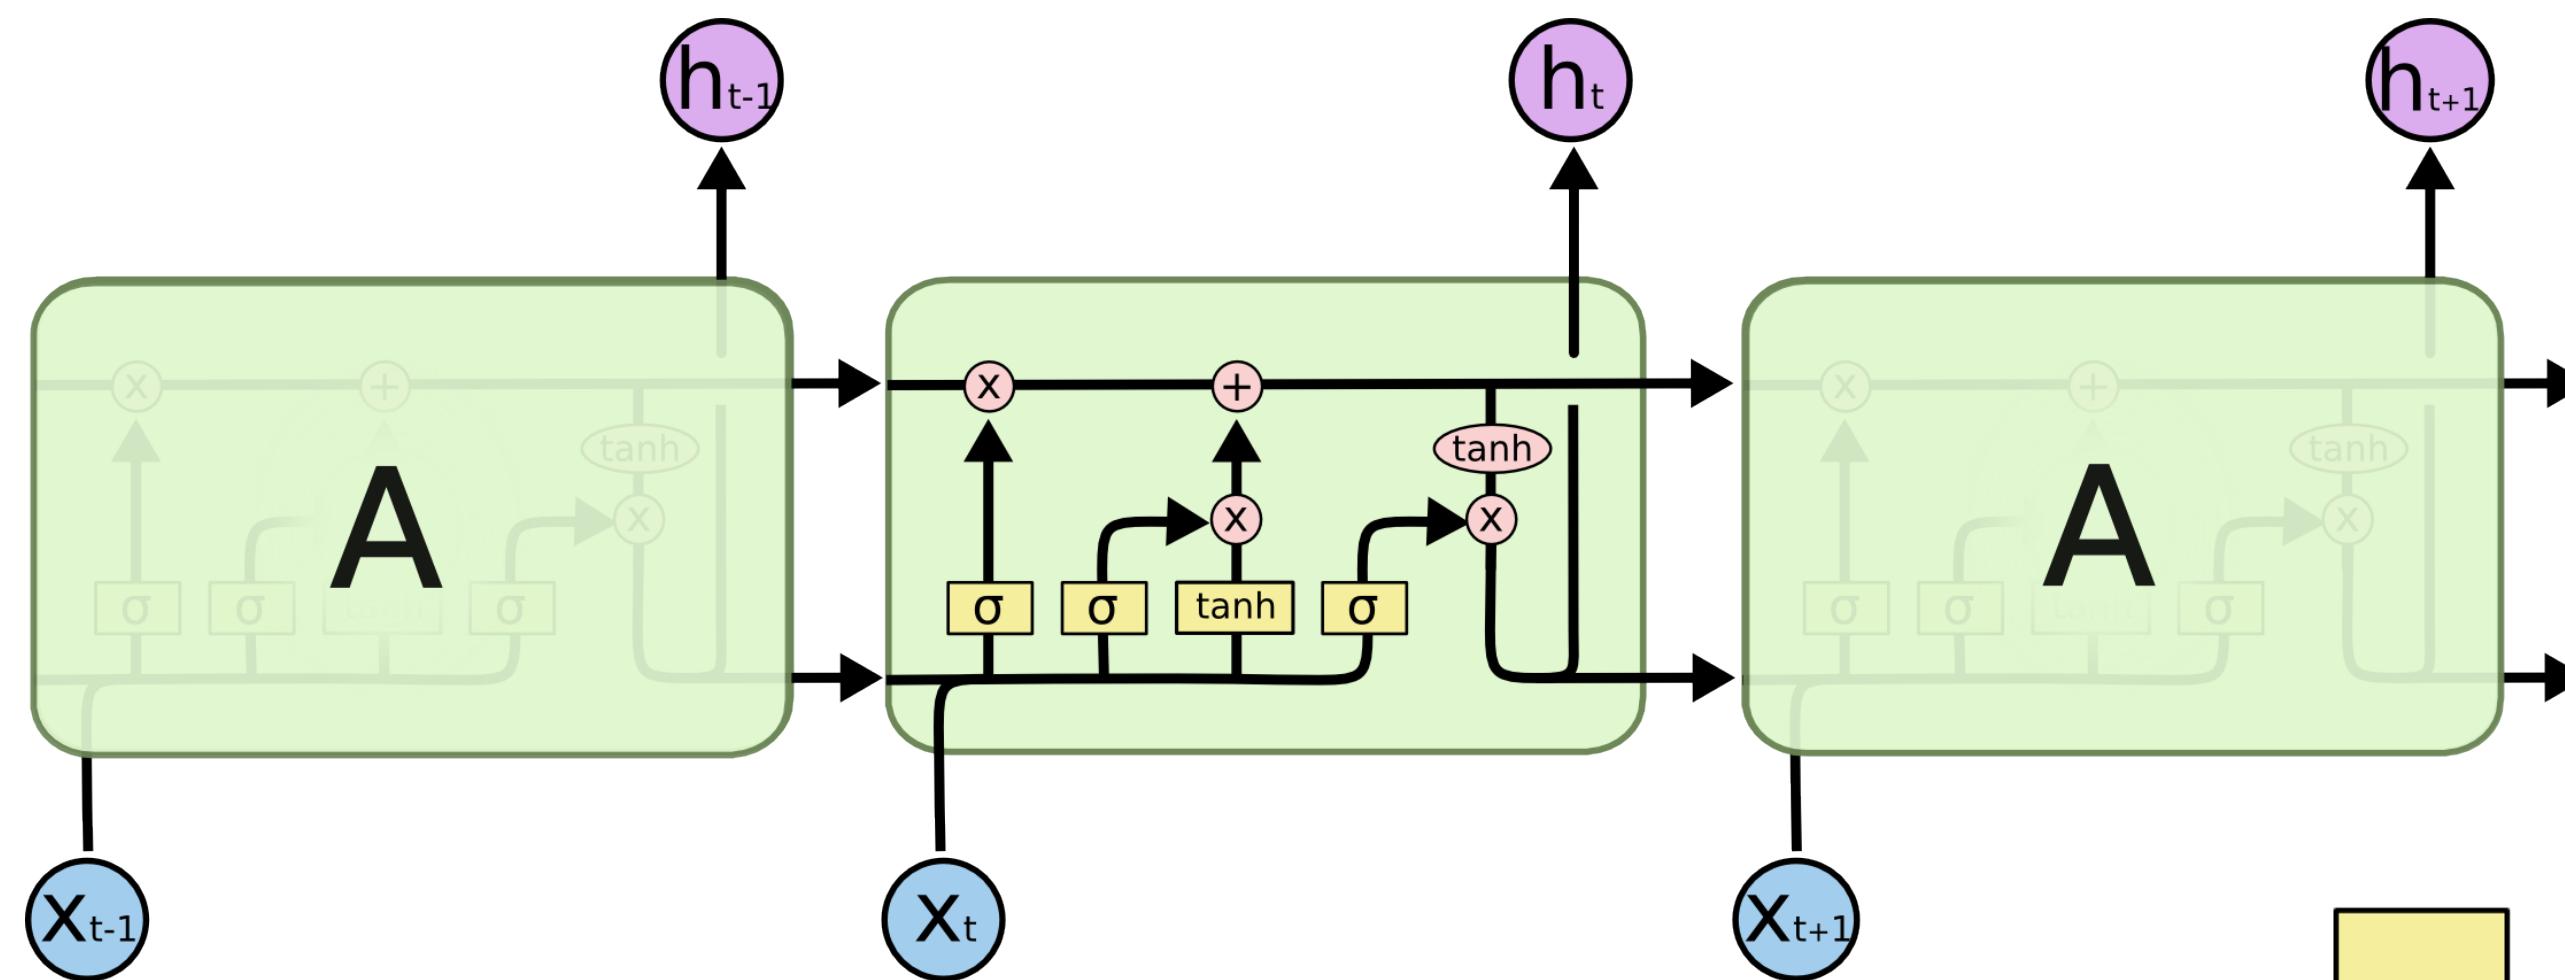

# Recurrent Neural Network

## LSTM

- RNN:

- LSTM:

Neural Network Layer

Pointwise Operation

Vector Transfer

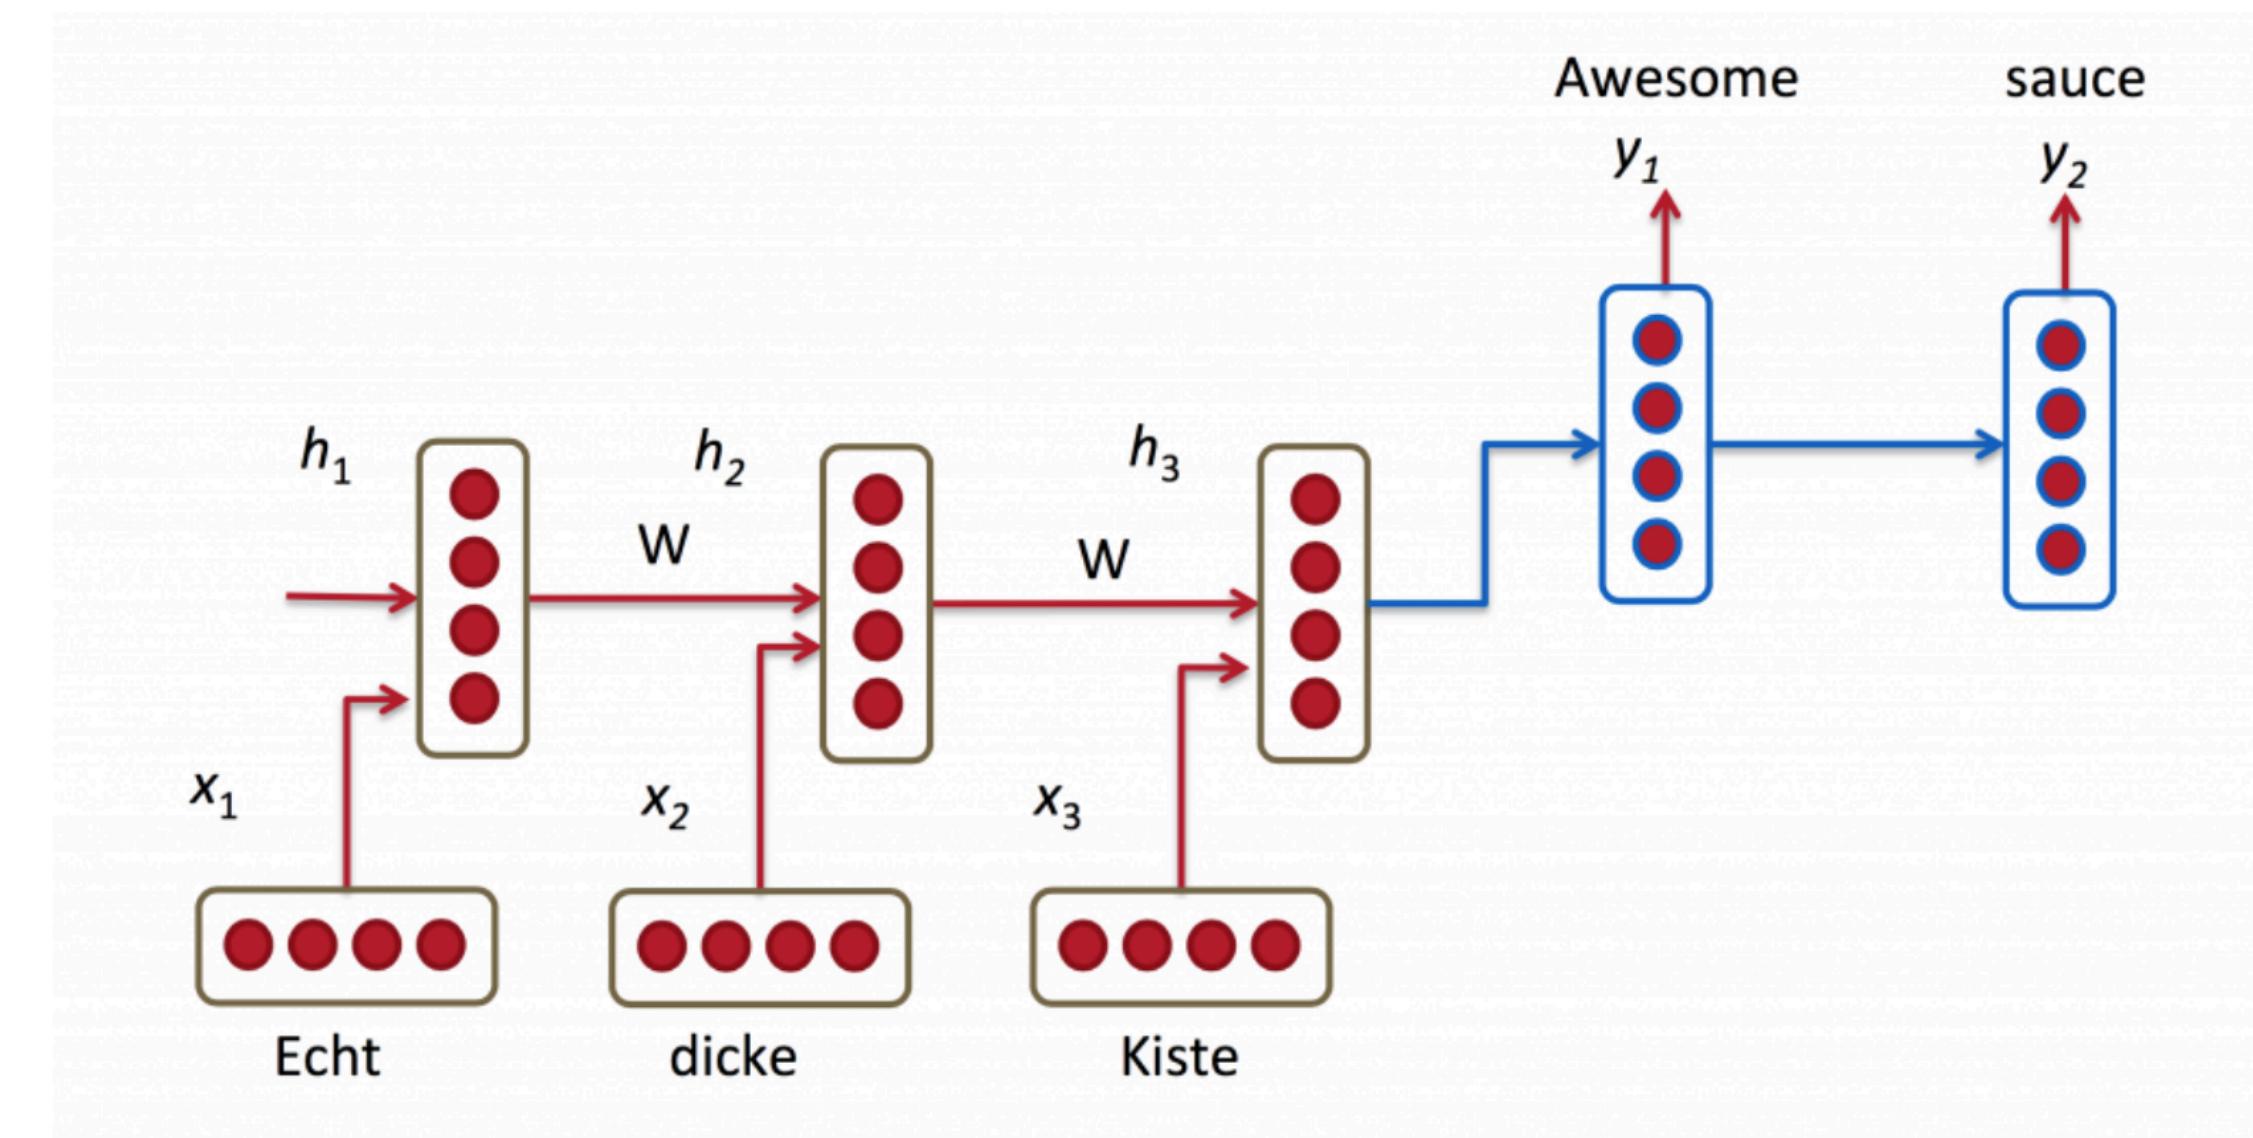

Concatenate

Copy

# Recurrent Neural Network

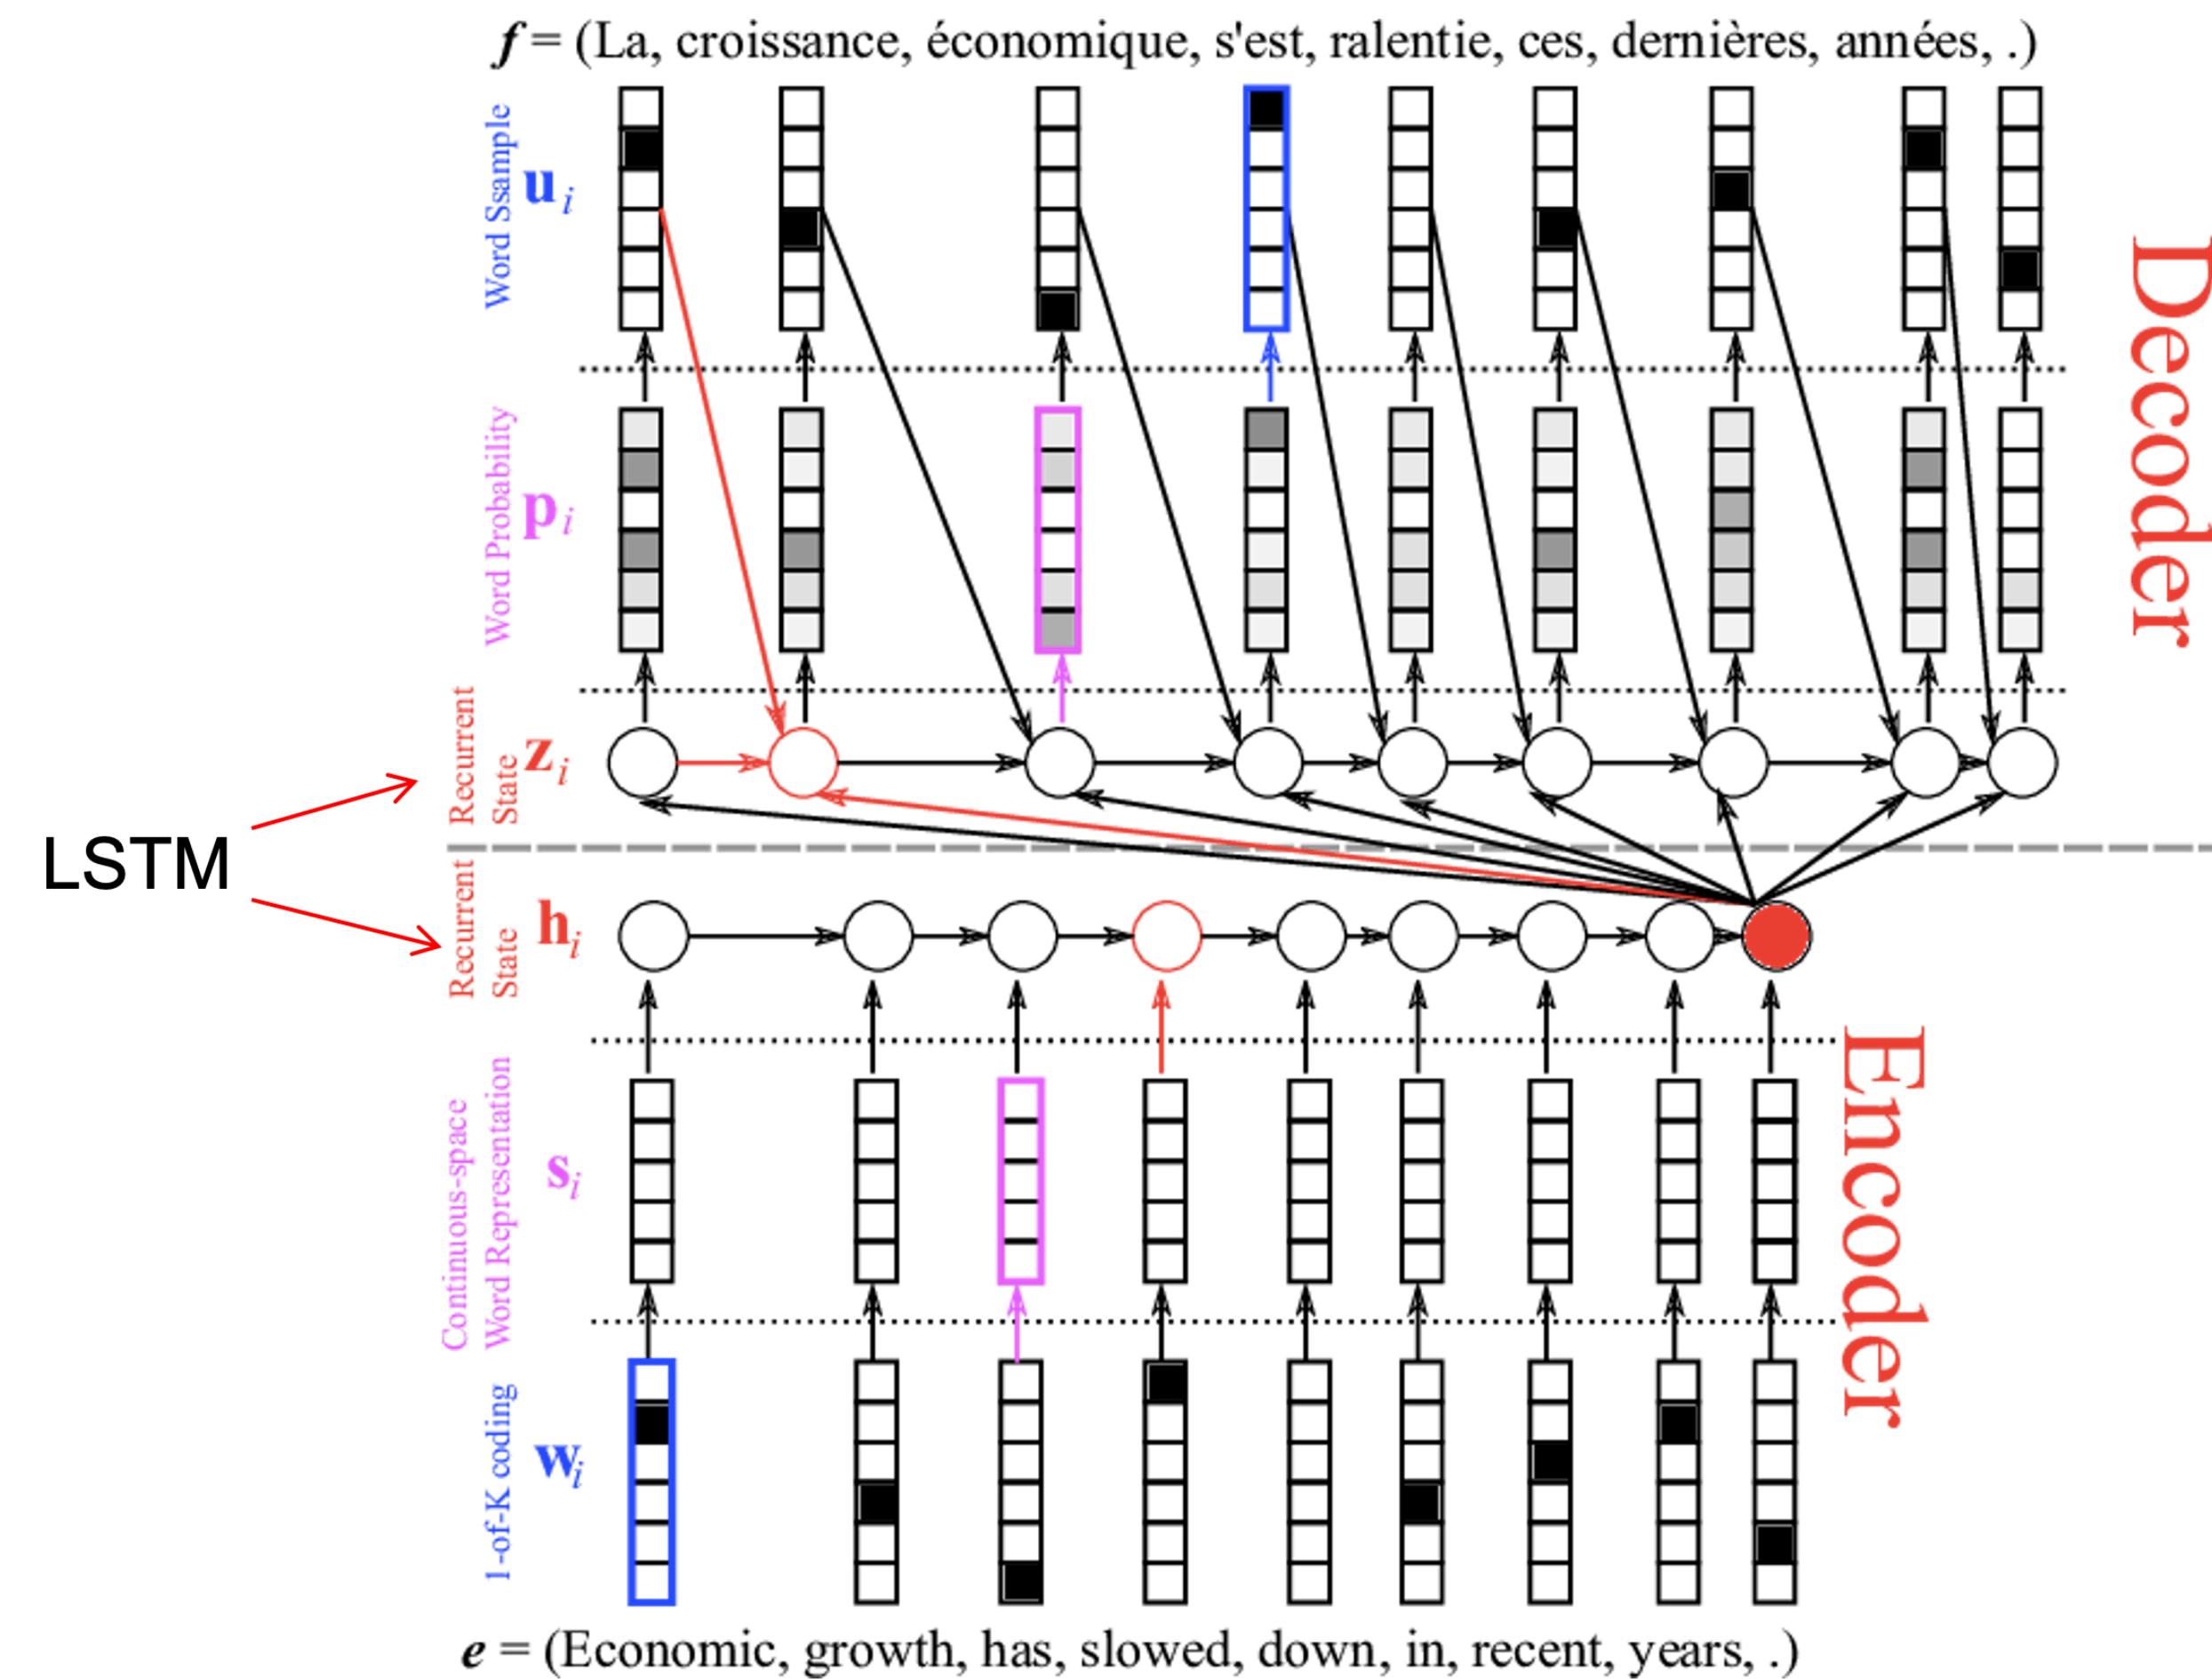

## Neural Machine Translation (NMT)

- Output the translated sentence from an input sentence
- Training data: a set of input-output pairs (supervised setting)
- Encoder-decoder approach:
  - Encoder: Use (RNN/LSTM) to encode the input sentence into a latent vector
  - Decoder: Use (RNN/LSTM) to generate a sentence based on the latent vector

# Recurrent Neural Network

## Neural Machine Translation

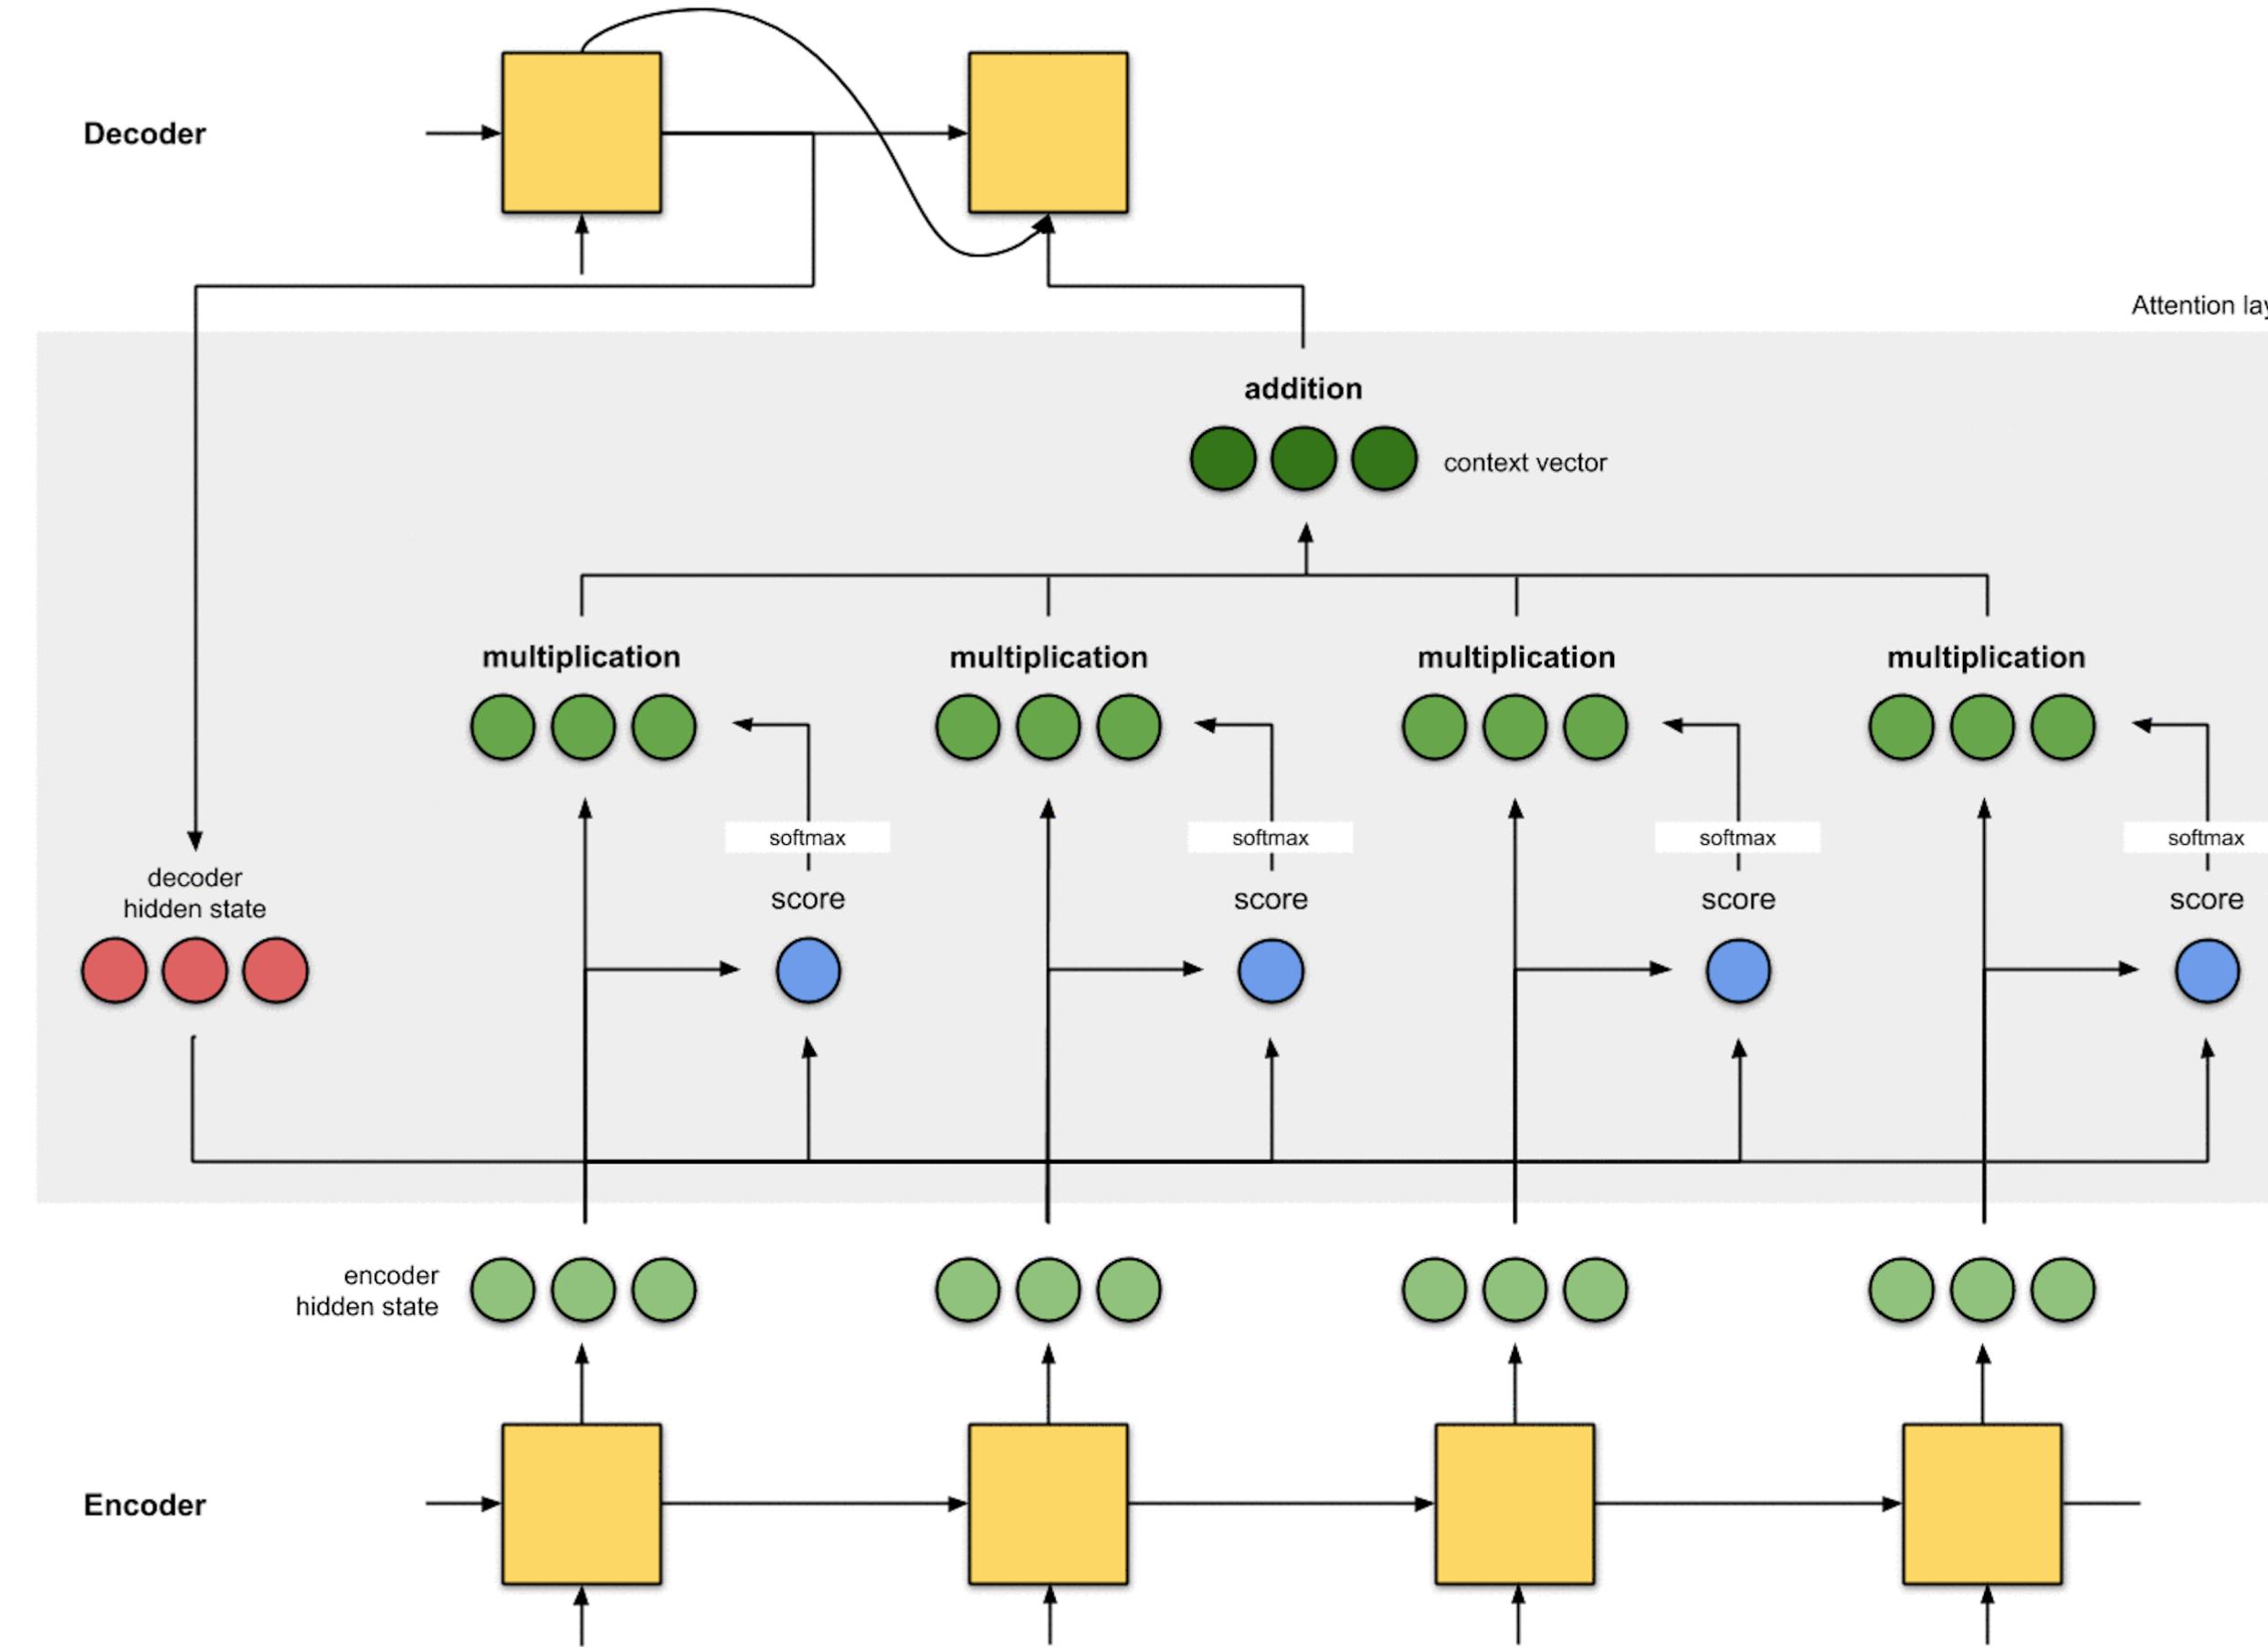

# Recurrent Neural Network

## Attention in NMT

- Usually, each output word is only related to a subset of input words (e.g., for machine translation)
- Let  $u$  be the **current decoder latent state**,  $v_1, \dots, v_n$  be the **latent state for each input word**
- Compute the weight of each state by
  - $p = \text{Softmax}(u^T v_1, \dots, u^T v_n)$
  - Compute the context vector by  $Vp = p_1 v_1 + \dots + p_n v_n$

# Recurrent Neural Network

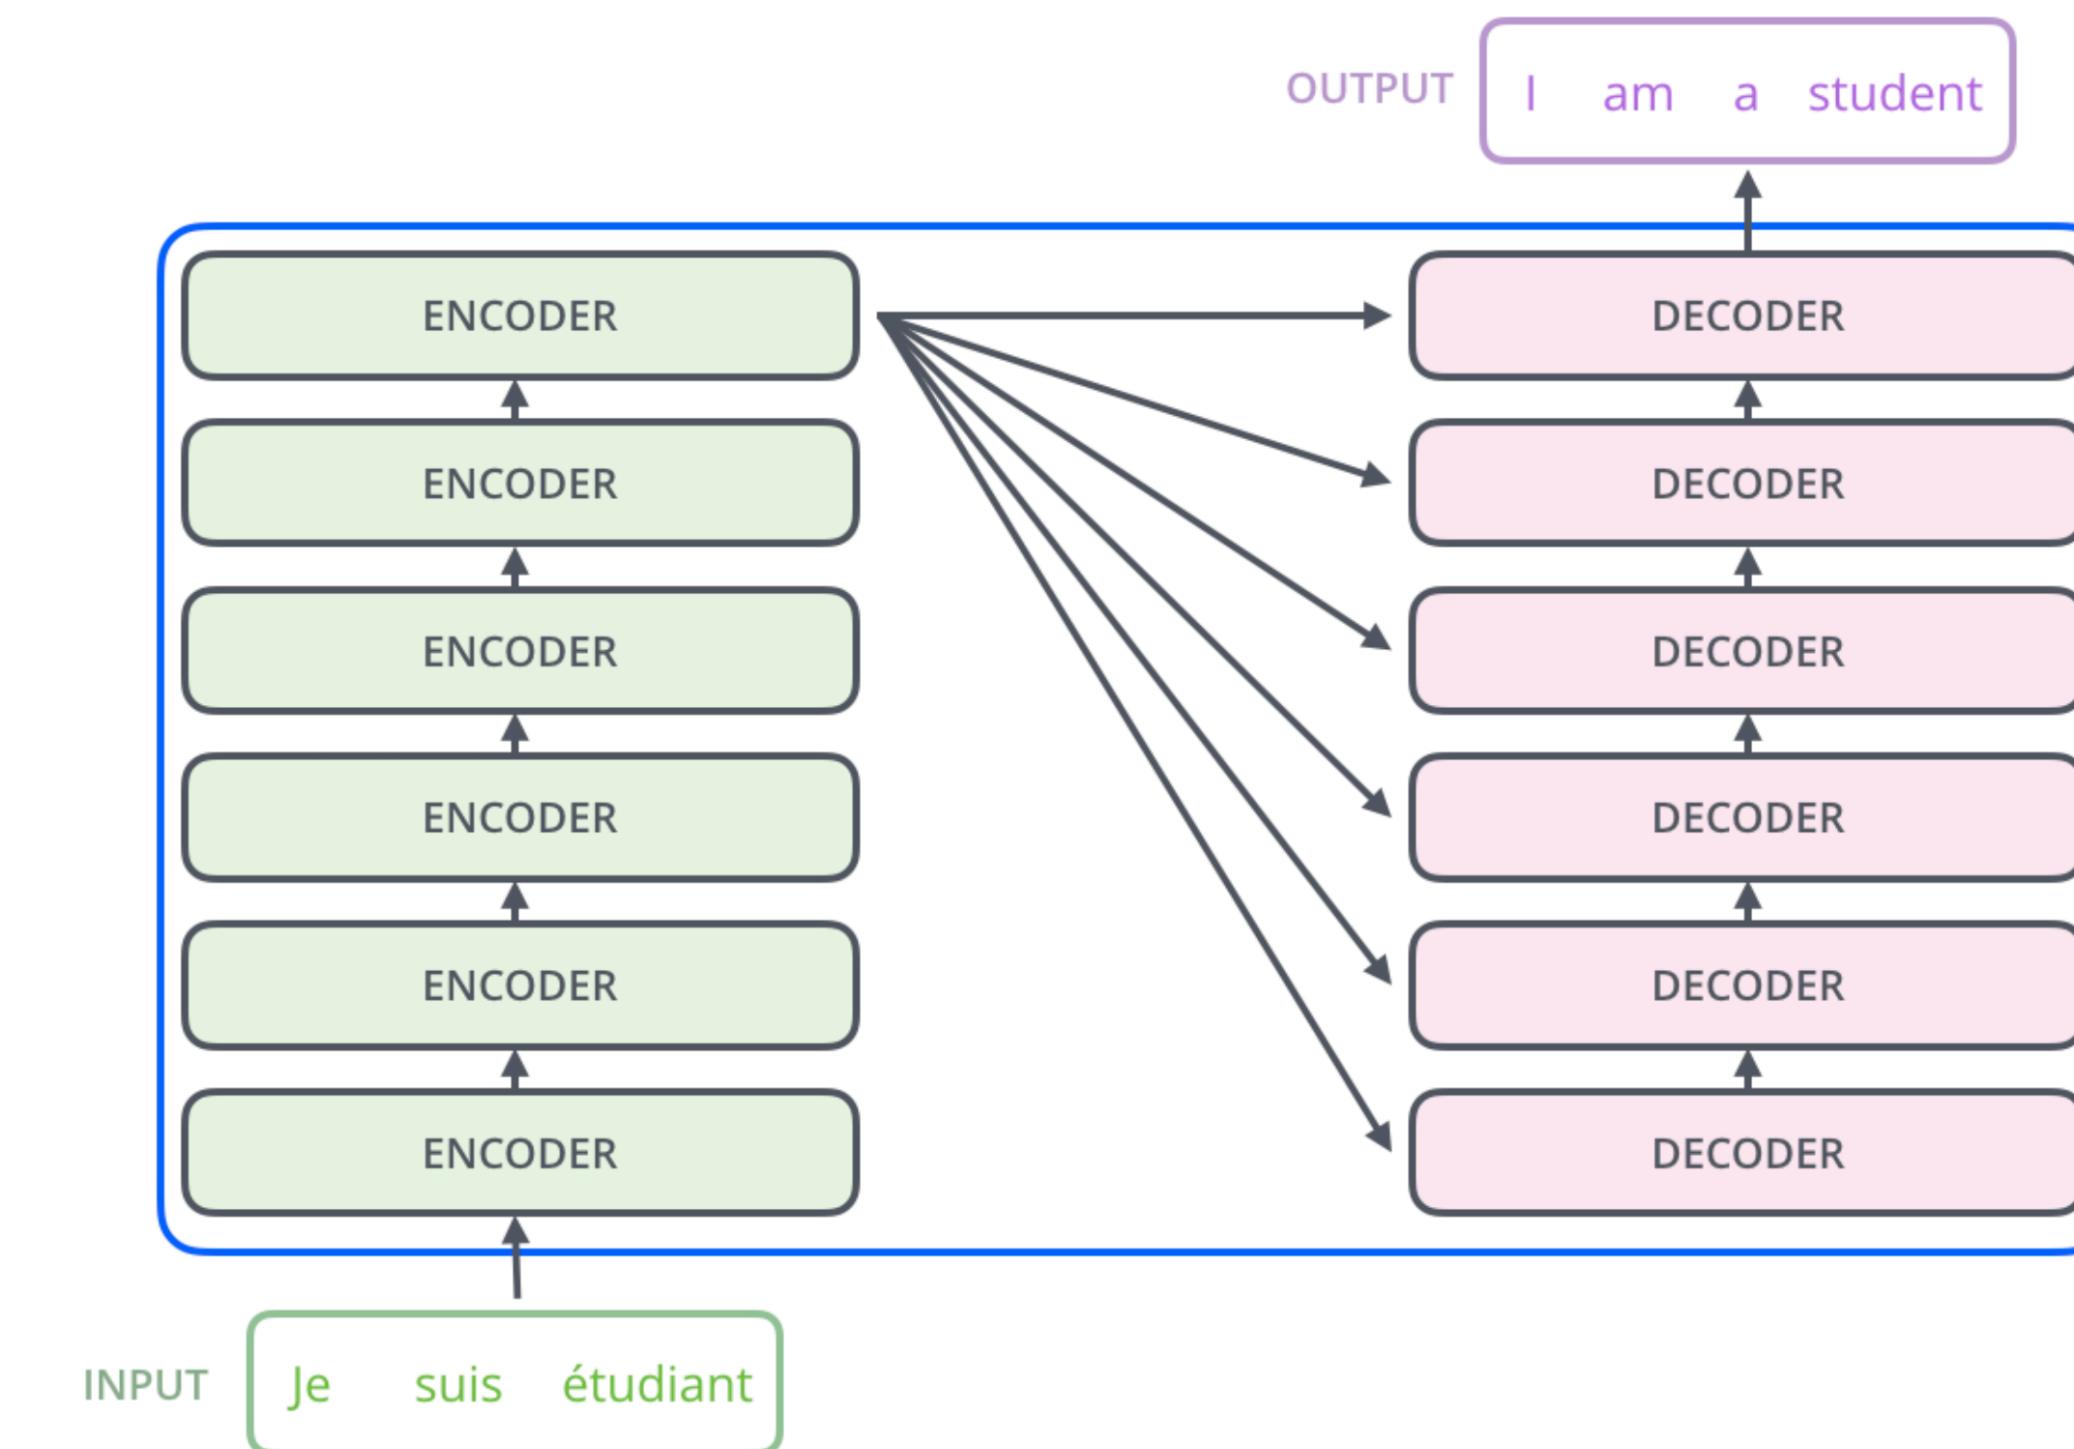

## Attention in NMT

# Transformer

## Transformer

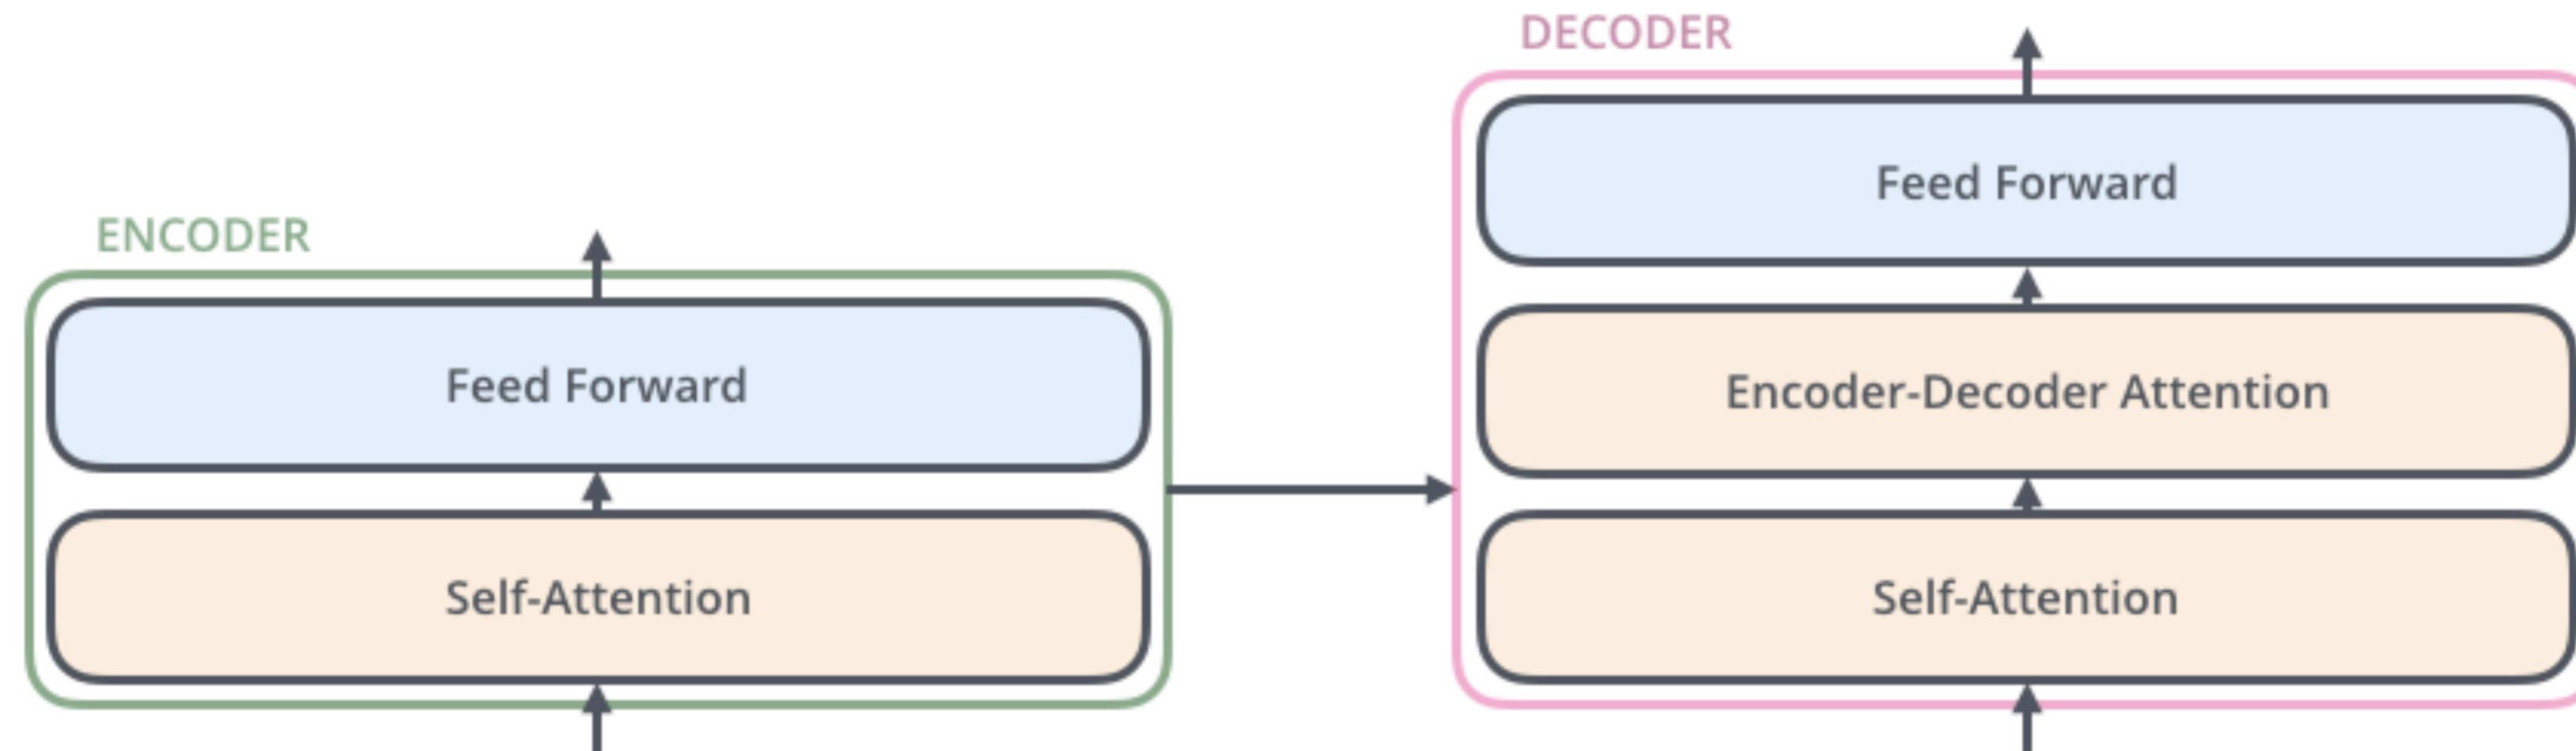

- An architecture that replies entirely on attention without using CNN/RNN
- Proposed in "Attention Is All You Need" (Vaswani et al., 2017)
- Initially used for neural machine translation

# Transformer

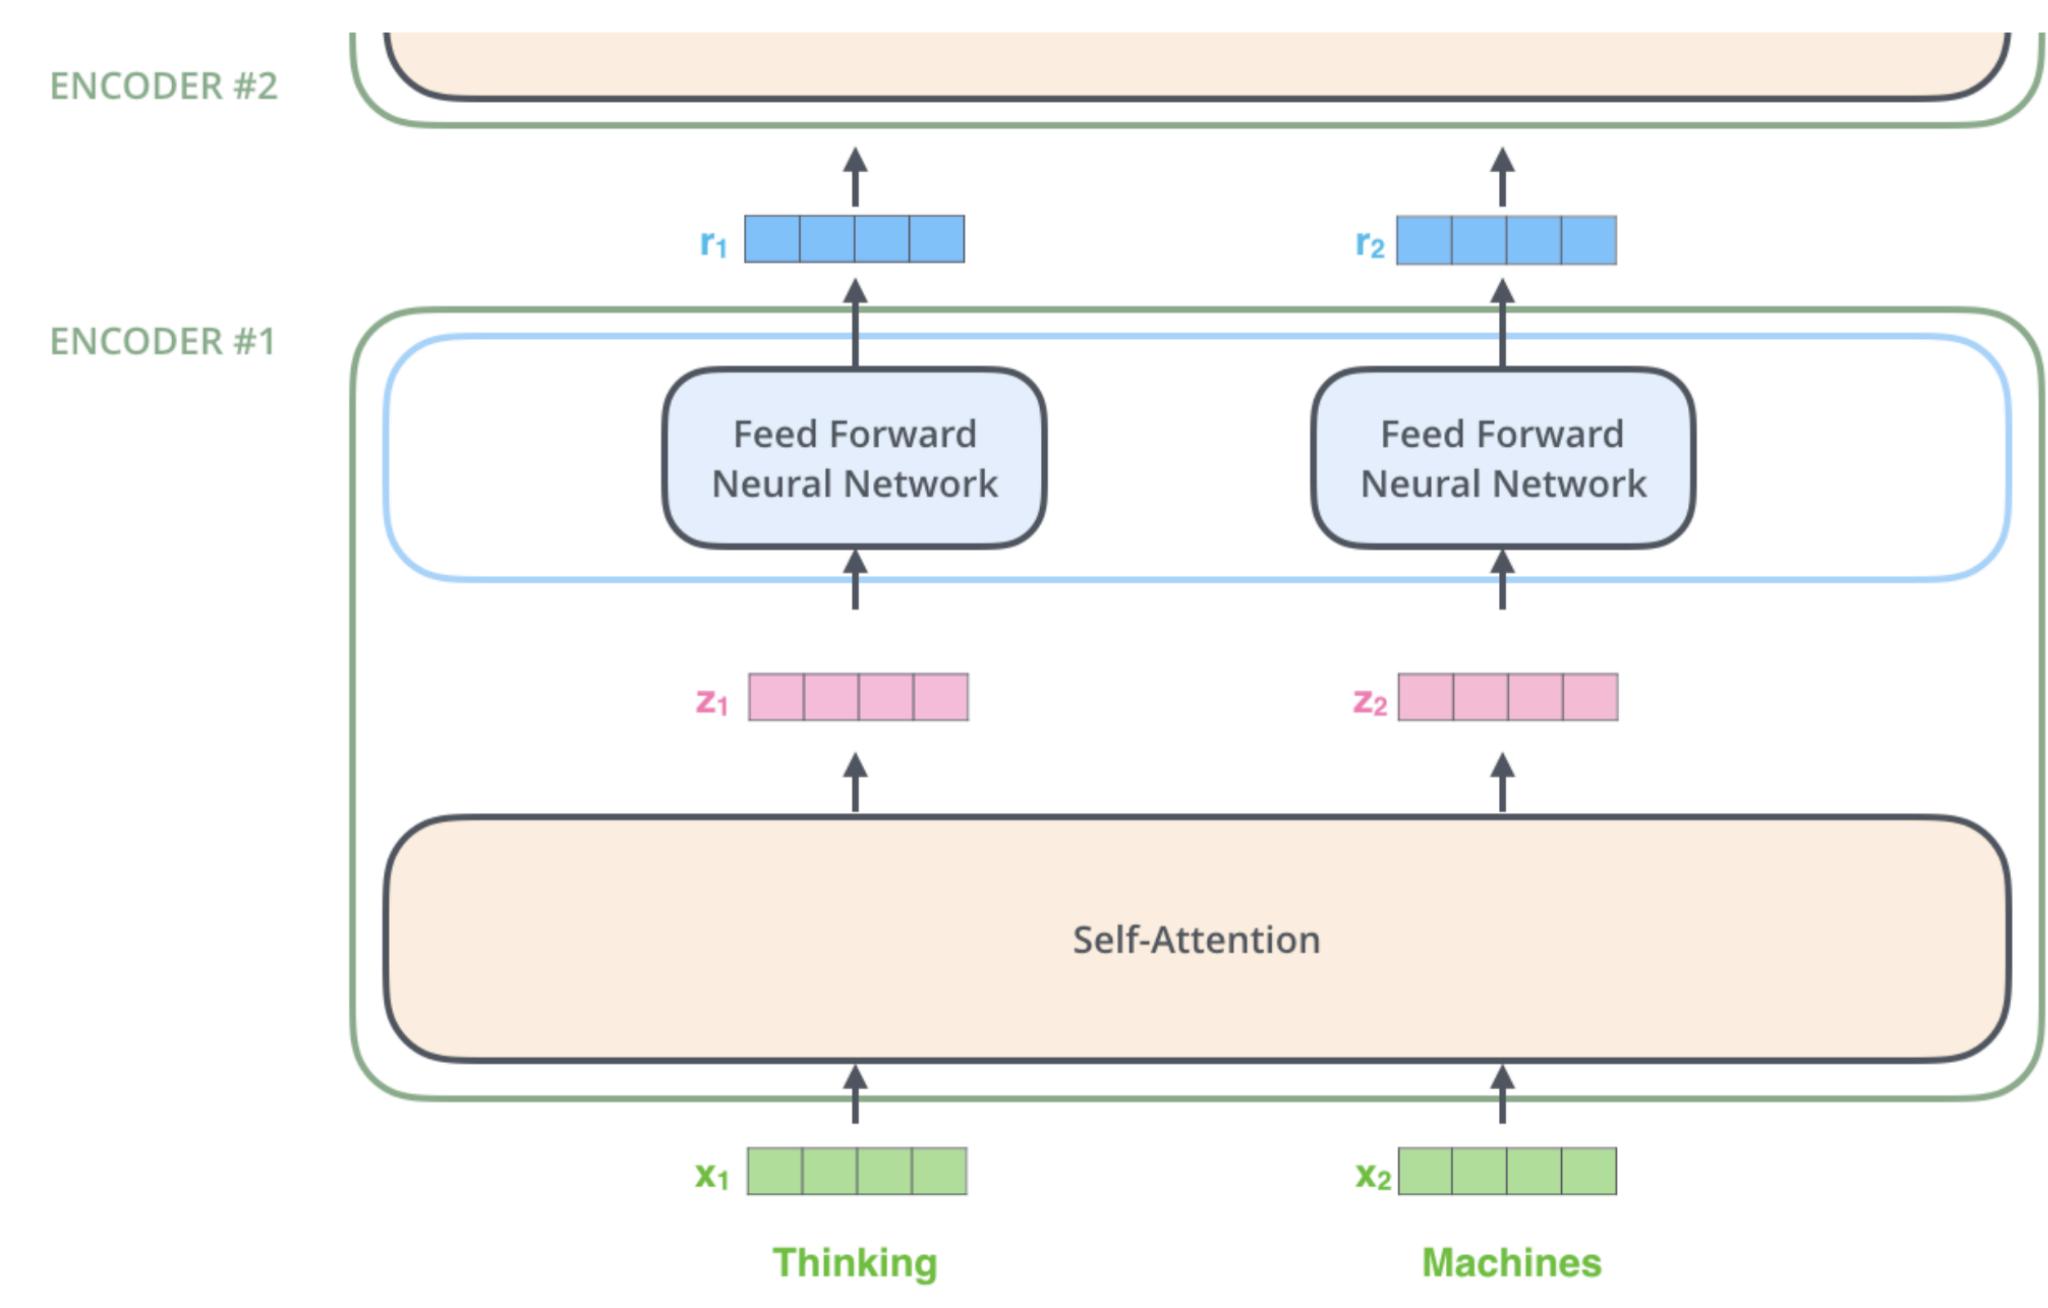

## Encoder and Decoder

- Self attention layer: the main architecture used in Transformer
- Decoder: will have another attention layer to help it focuses on relevant parts of input sentences.

# Transformer Encoder

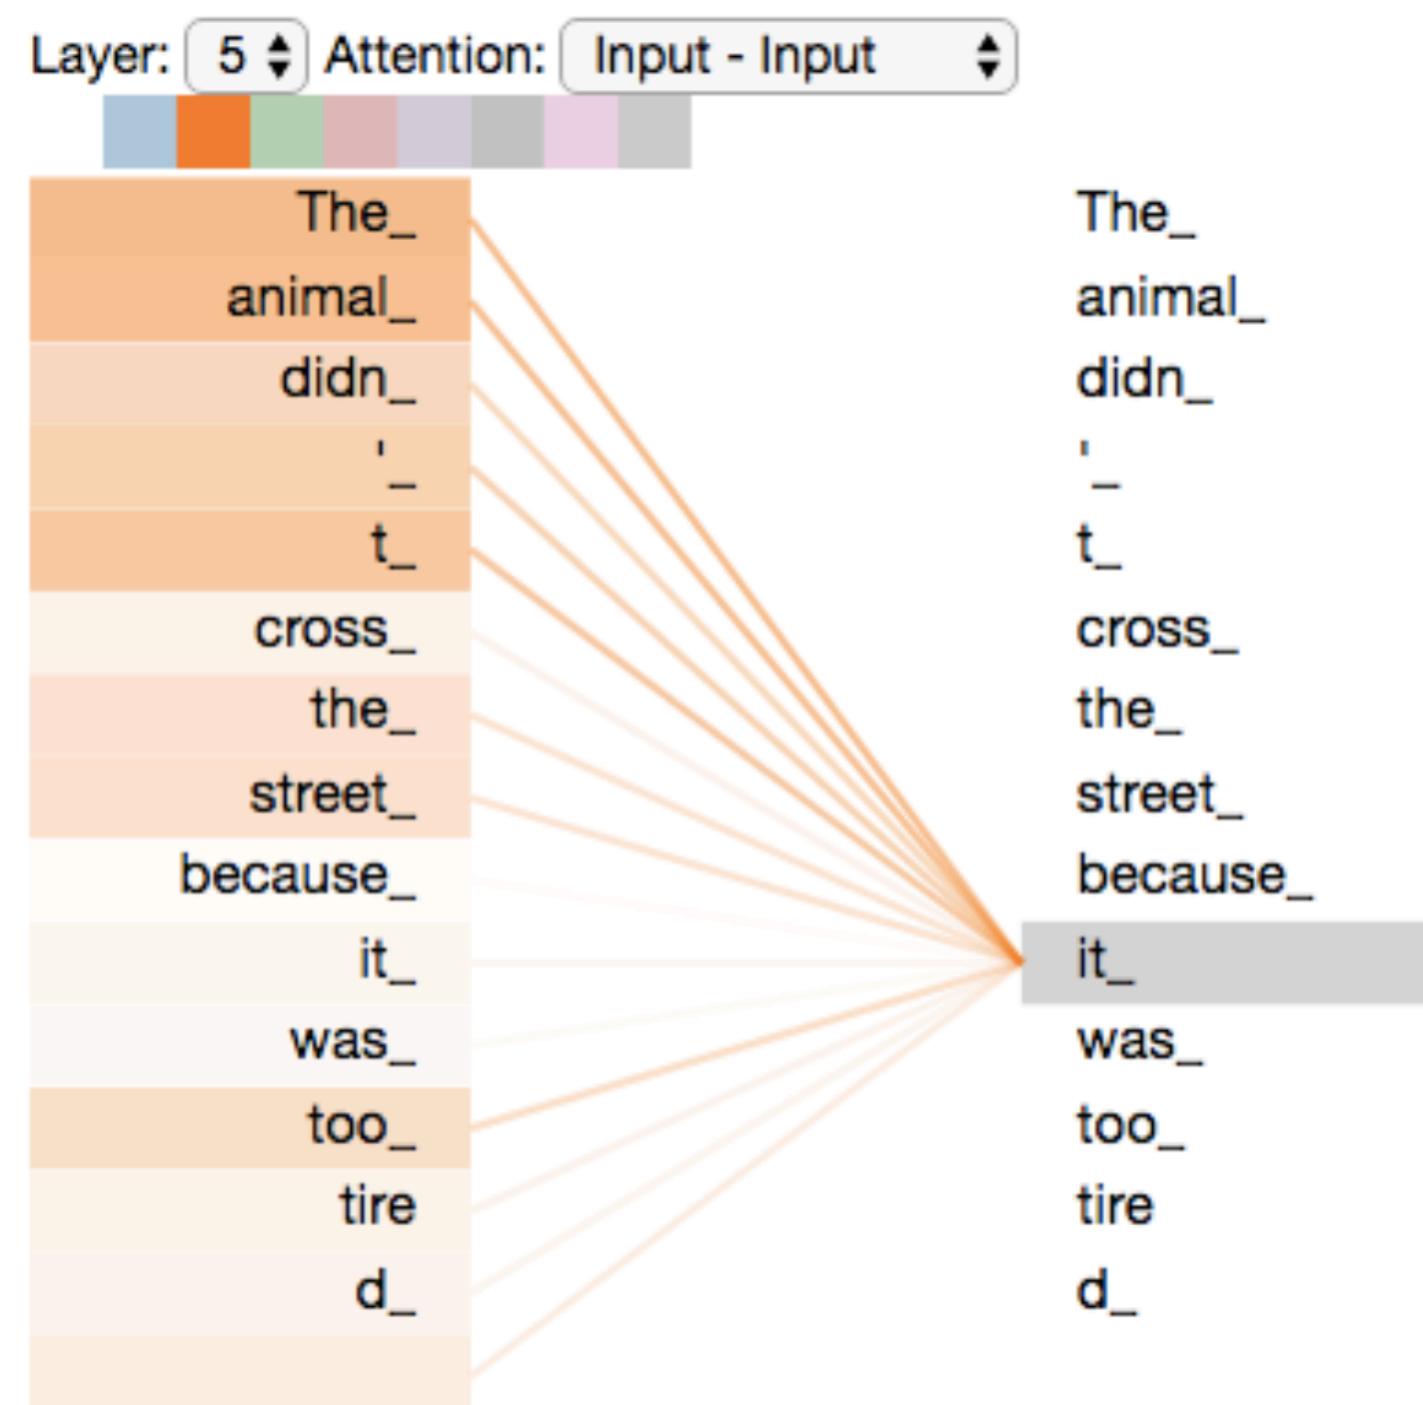

- Each word has a corresponding “latent vector” (initially the word embedding for each word)
- Each layer of encoder:
  - Receive a list of vectors as input
  - Passing these vectors to a **self-attention** layer
  - Then passing them into a feed-forward layer
  - Output a list of vectors

# Transformer

## Self-attention layer

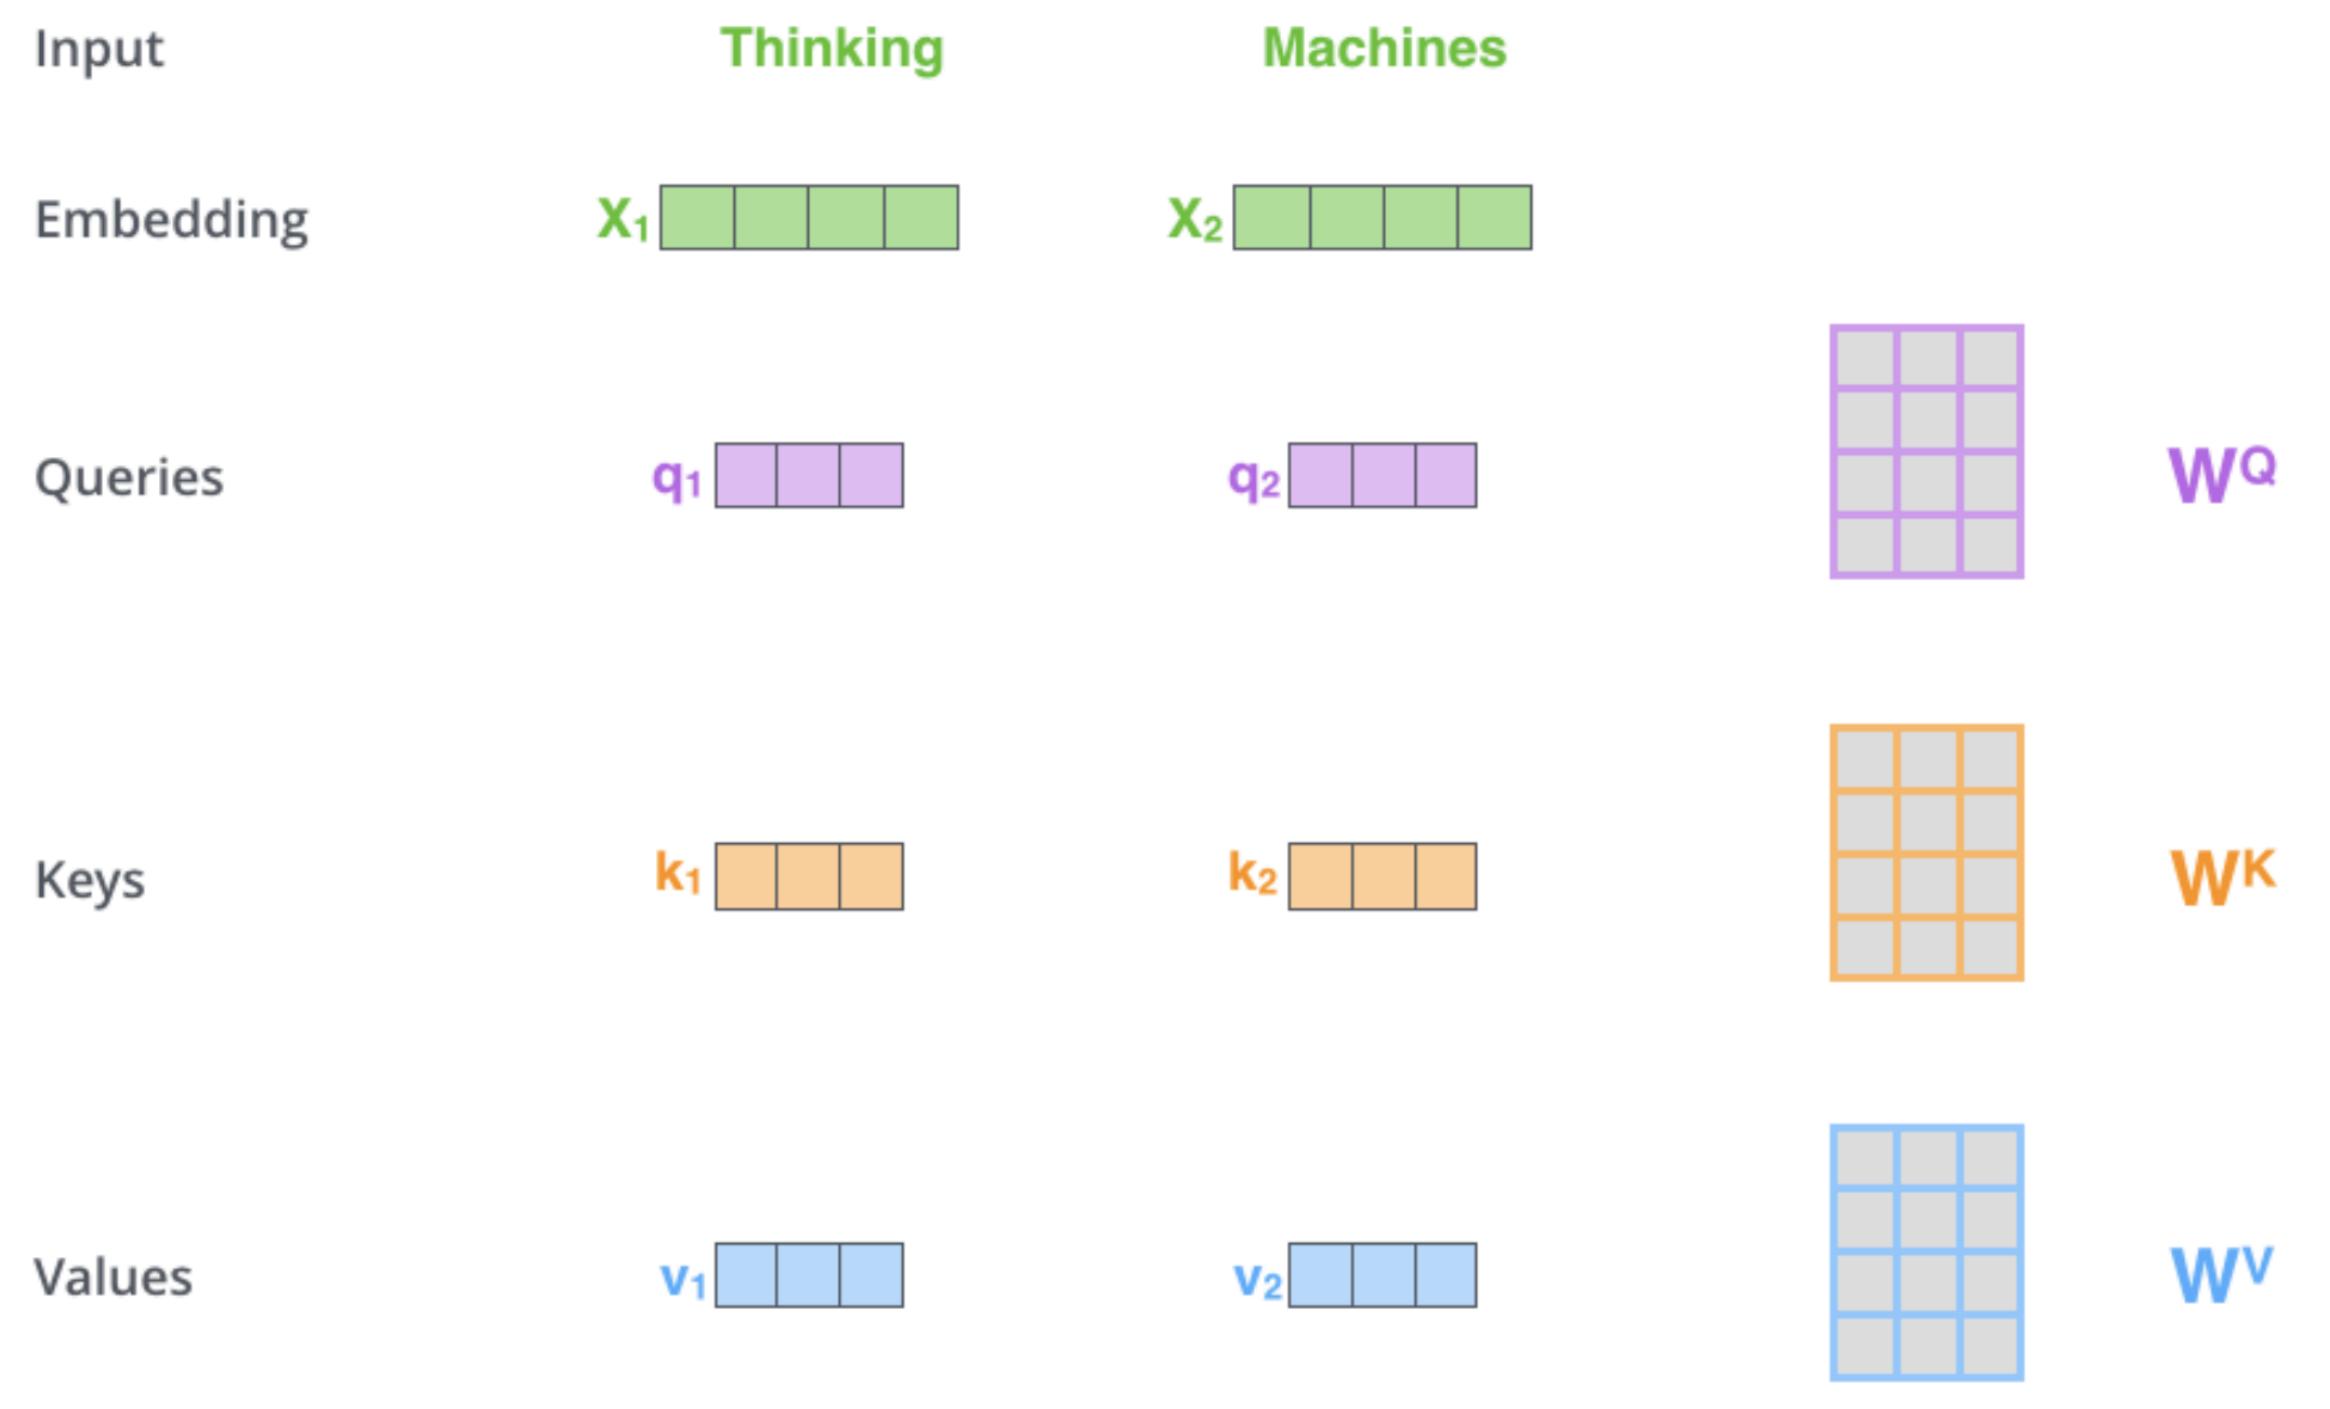

- Main idea: The actual meaning of each word may be related to other words in the sentence
- The actual meaning (latent vector) of each word is a weighted (attention) combination of other words (latent vectors) in the sentences

# Transformer

## Self-attention layer

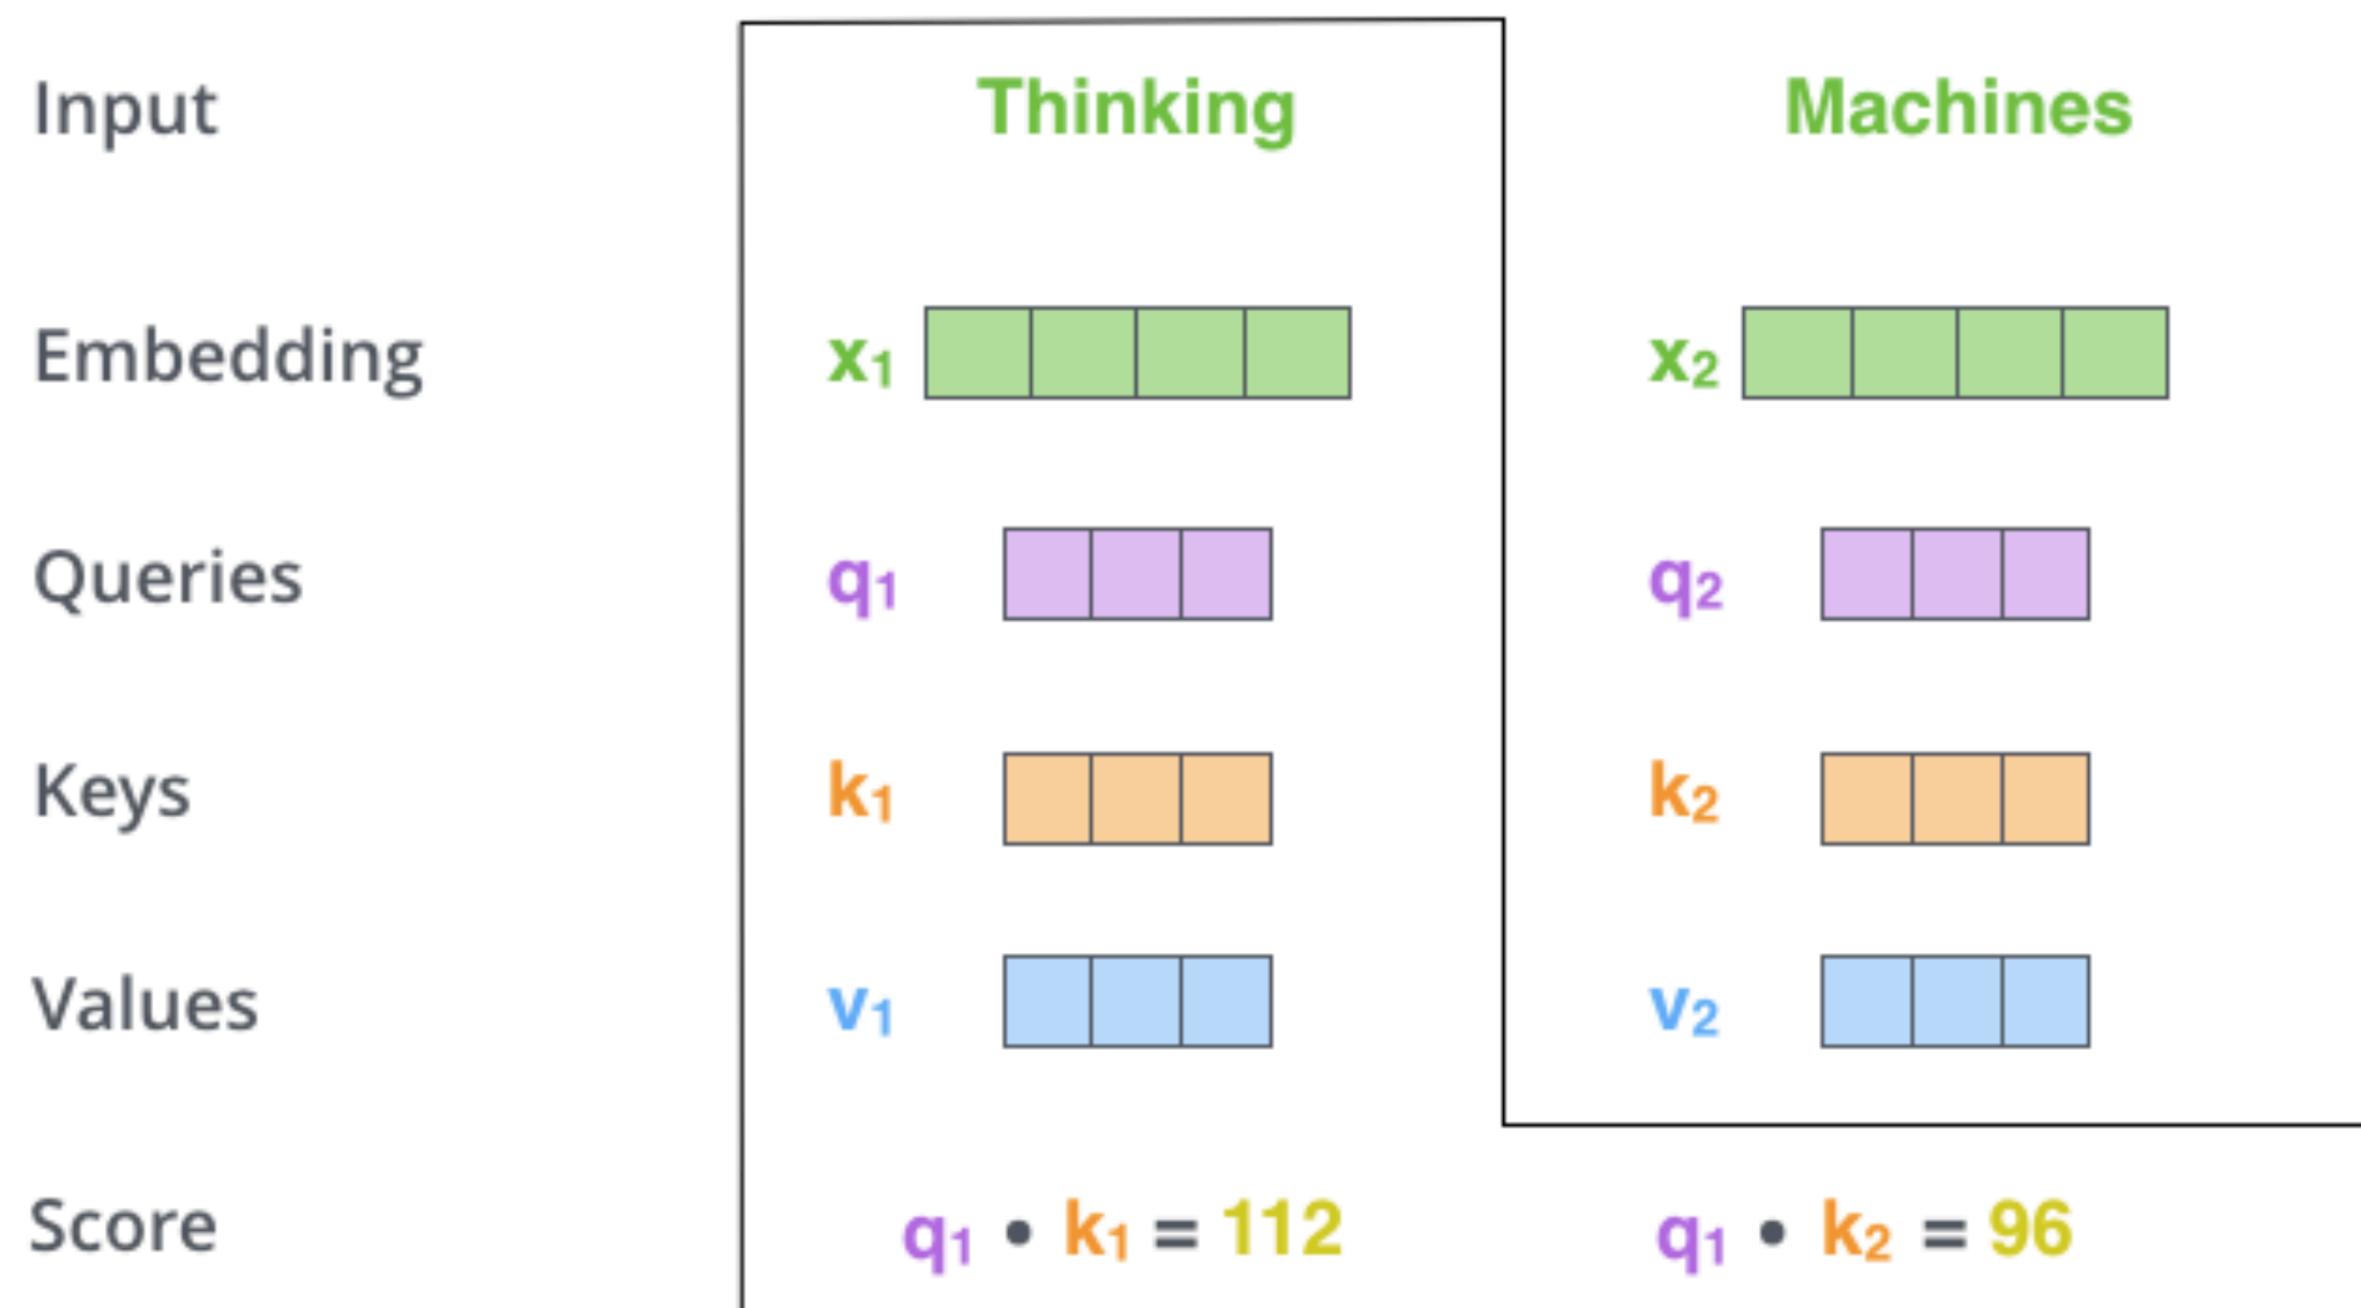

- Input latent vectors:  $x_1, \dots, x_n$
- Self-attention parameters:  
 $W^Q, W^K, W^V$  (weights for query, key, value)
- For each word  $i$ , compute
  - Query vector:  $q_i = x_i W^Q$
  - Key vector:  $k_i = x_i W^K$
  - Value vector:  $v_i = x_i W^V$

# Transformer

## Self-attention layer

- For each word  $i$ , compute the scores to determine how much focus to place on other input words
  - The **attention score** for word  $j$  to word  $i$ :  $q_i^T k_j$

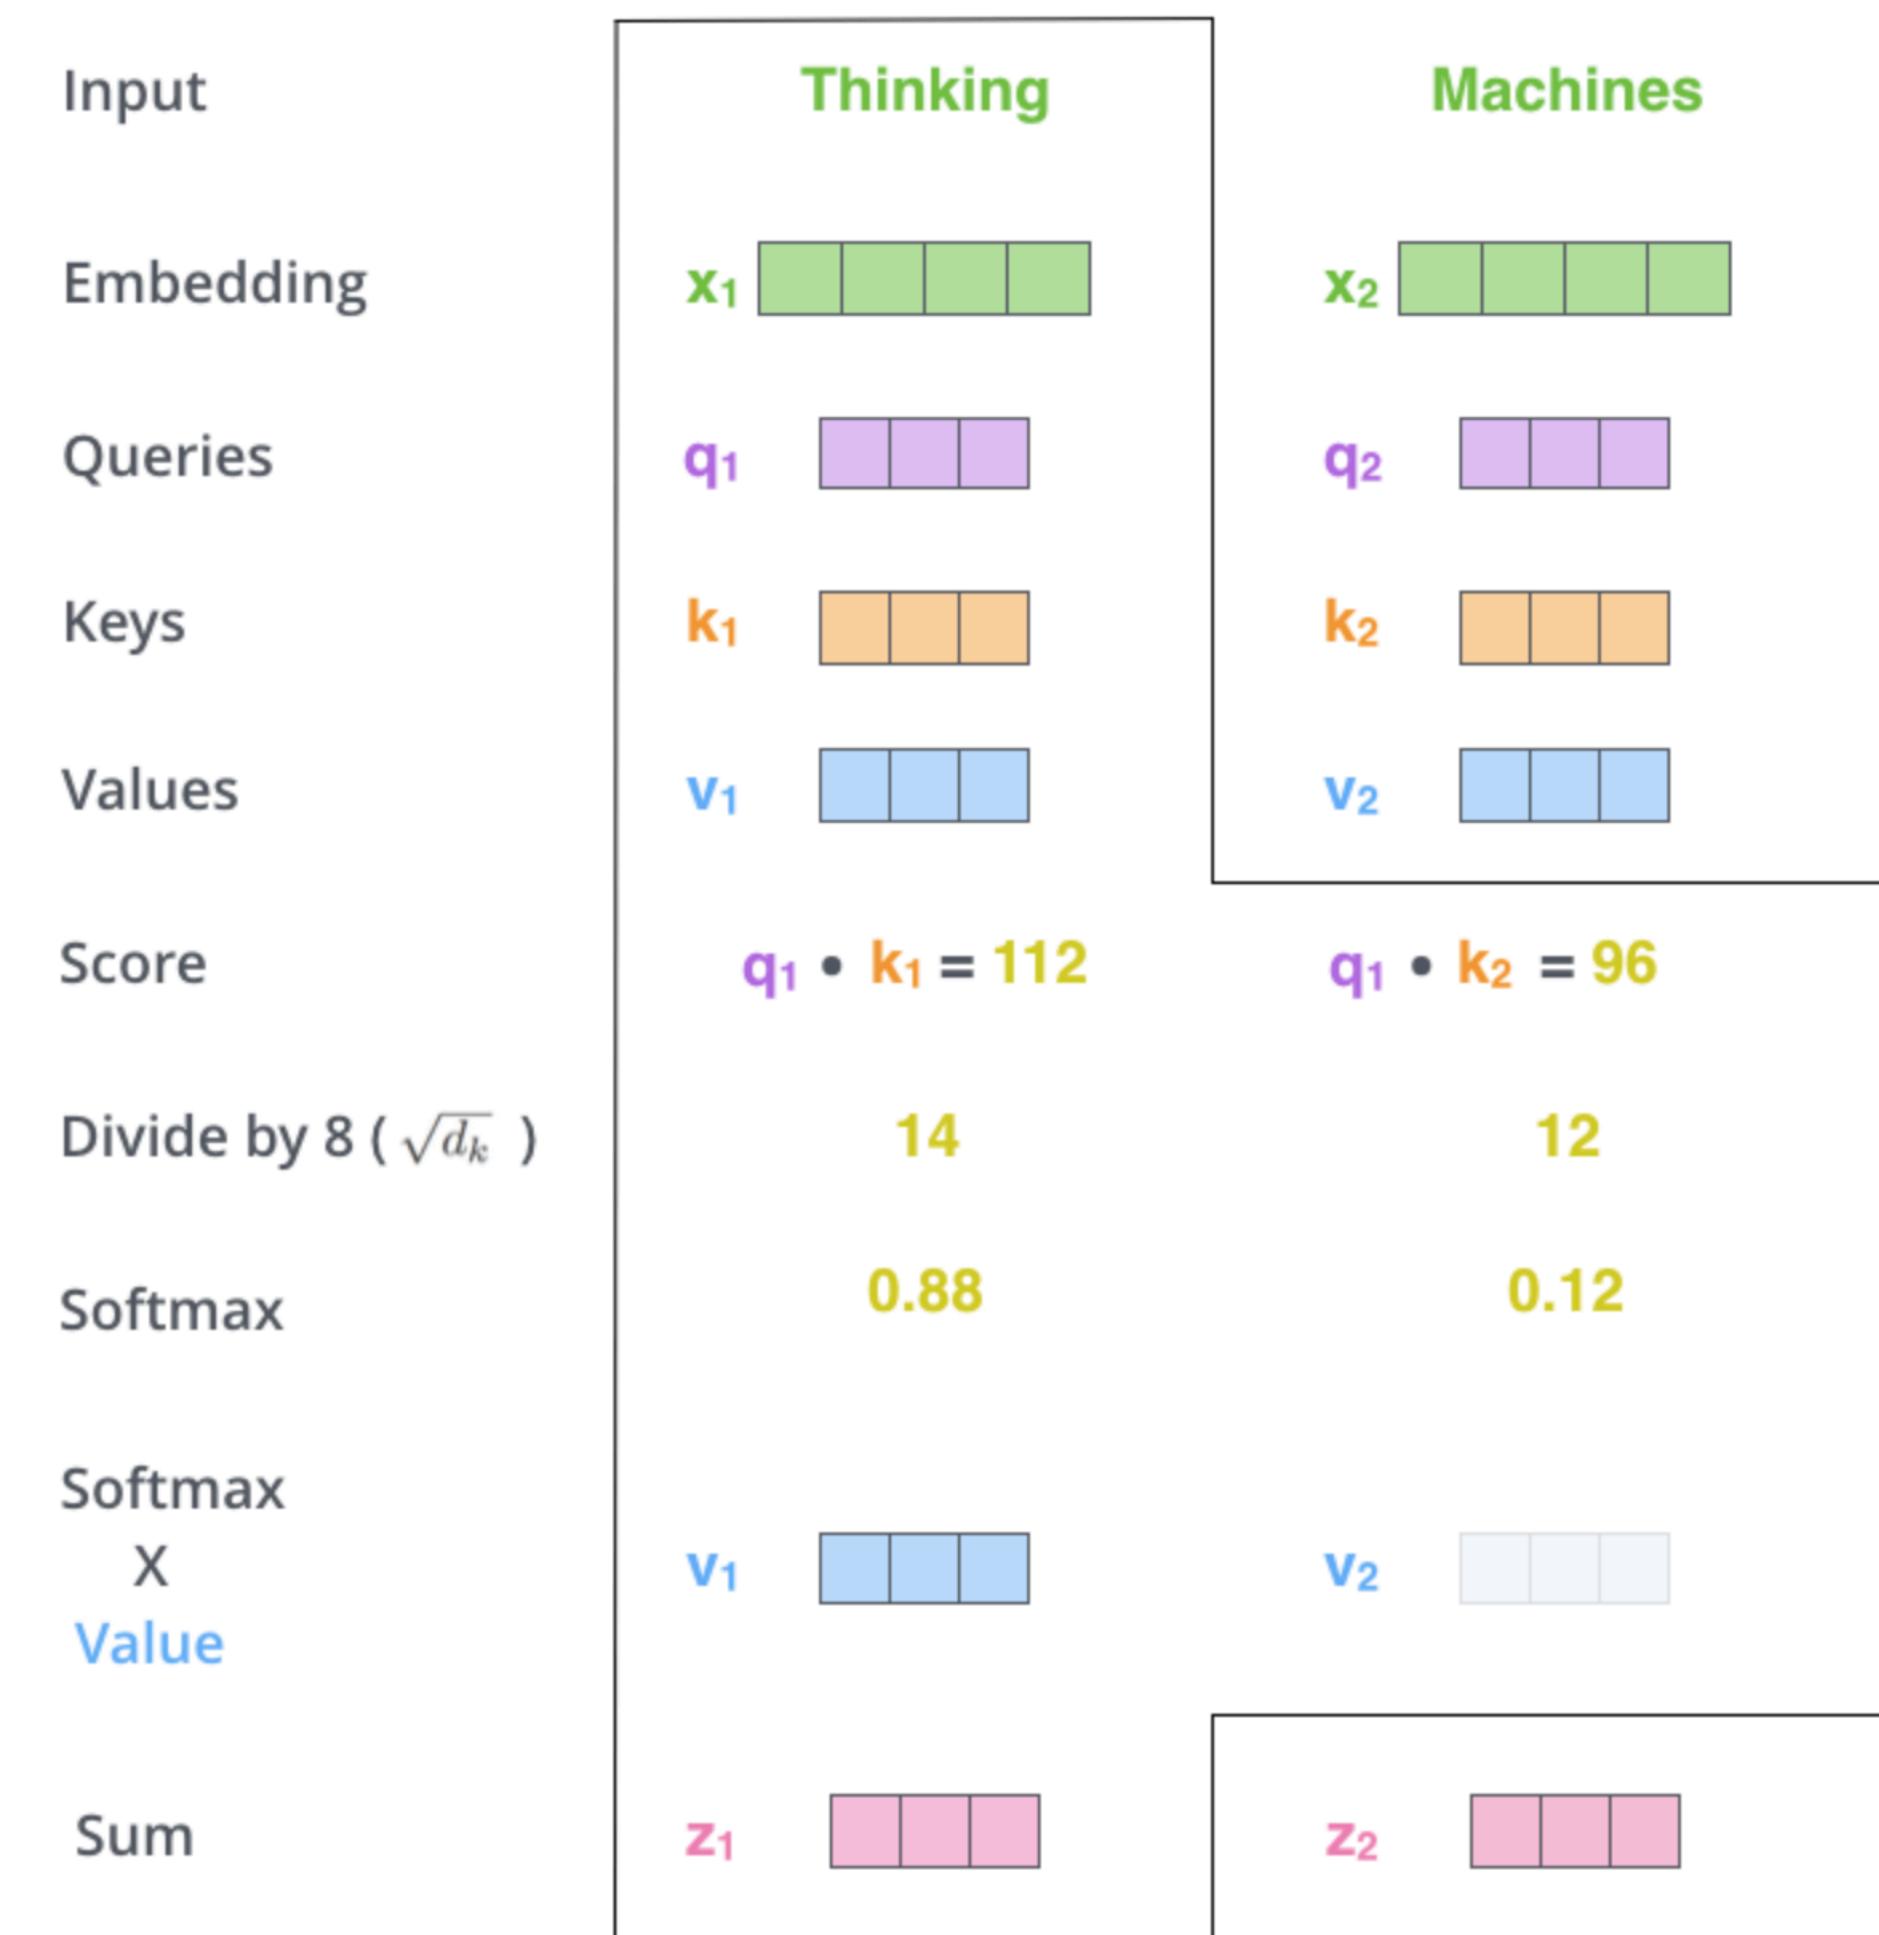

# Transformer

## Self-attention layer

- For each word  $i$ , the output vector

- $\sum_j s_{ij} v_j, \quad s_i = \text{softmax}(q_i^T k_1, \dots, q_i^T k_n)$

# Transformer

## Matrix form

- $Q = XW^Q, K = XW^K, V = XW^V, Z = \text{softmax}(QK^T)V$

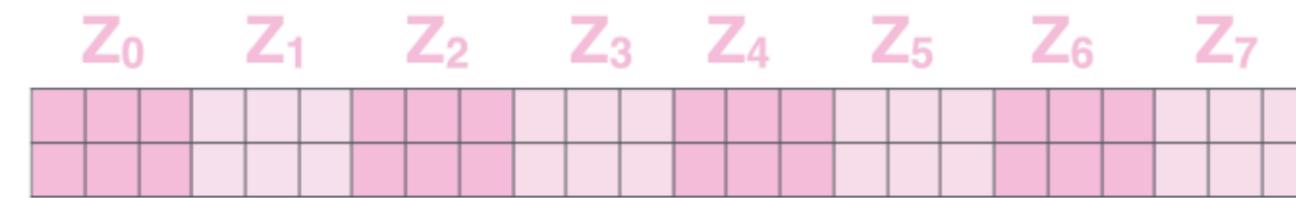

$$\begin{array}{ccc} \mathbf{X} & \mathbf{W}^Q & \mathbf{Q} \\ \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} & \times & \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} \\ \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} & = & \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} \end{array}$$
$$\begin{array}{ccc} \mathbf{X} & \mathbf{W}^K & \mathbf{K} \\ \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} & \times & \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} \\ \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} & = & \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} \end{array}$$
$$\begin{array}{ccc} \mathbf{X} & \mathbf{W}^V & \mathbf{V} \\ \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} & \times & \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} \\ \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} & = & \begin{matrix} \text{---} \\ \text{---} \\ \text{---} \end{matrix} \end{array}$$
$$\text{softmax}\left(\frac{\mathbf{Q} \times \mathbf{K}^T}{\sqrt{d_k}}\right) \mathbf{V} = \mathbf{Z}$$

# Transformer

## Multiply with weight matrix to reshape

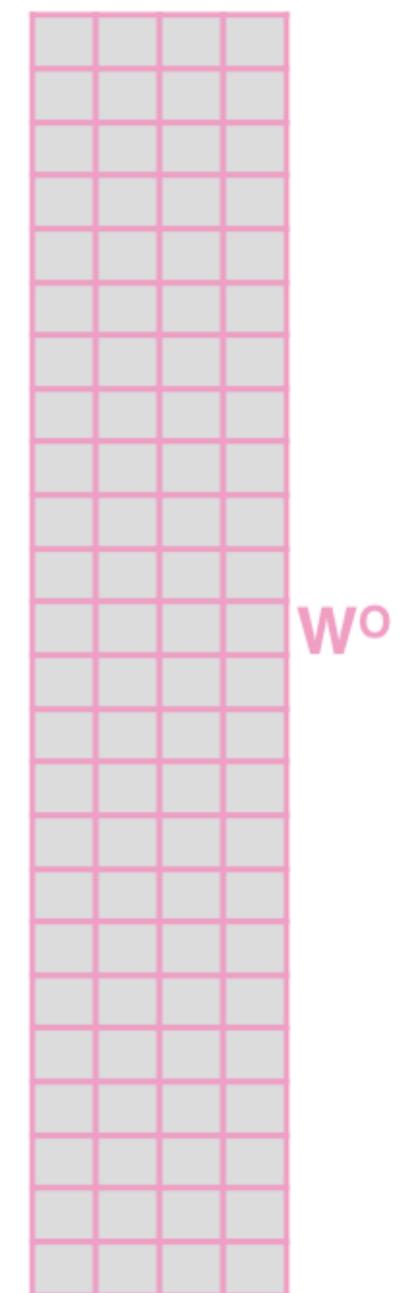

- Gather all the outputs  $Z_1, \dots, Z_k$
- Multiply with a weight matrix to reshape
- Then pass to the next fully connected layer

1) Concatenate all the attention heads

2) Multiply with a weight matrix  $W^o$  that was trained jointly with the model

x

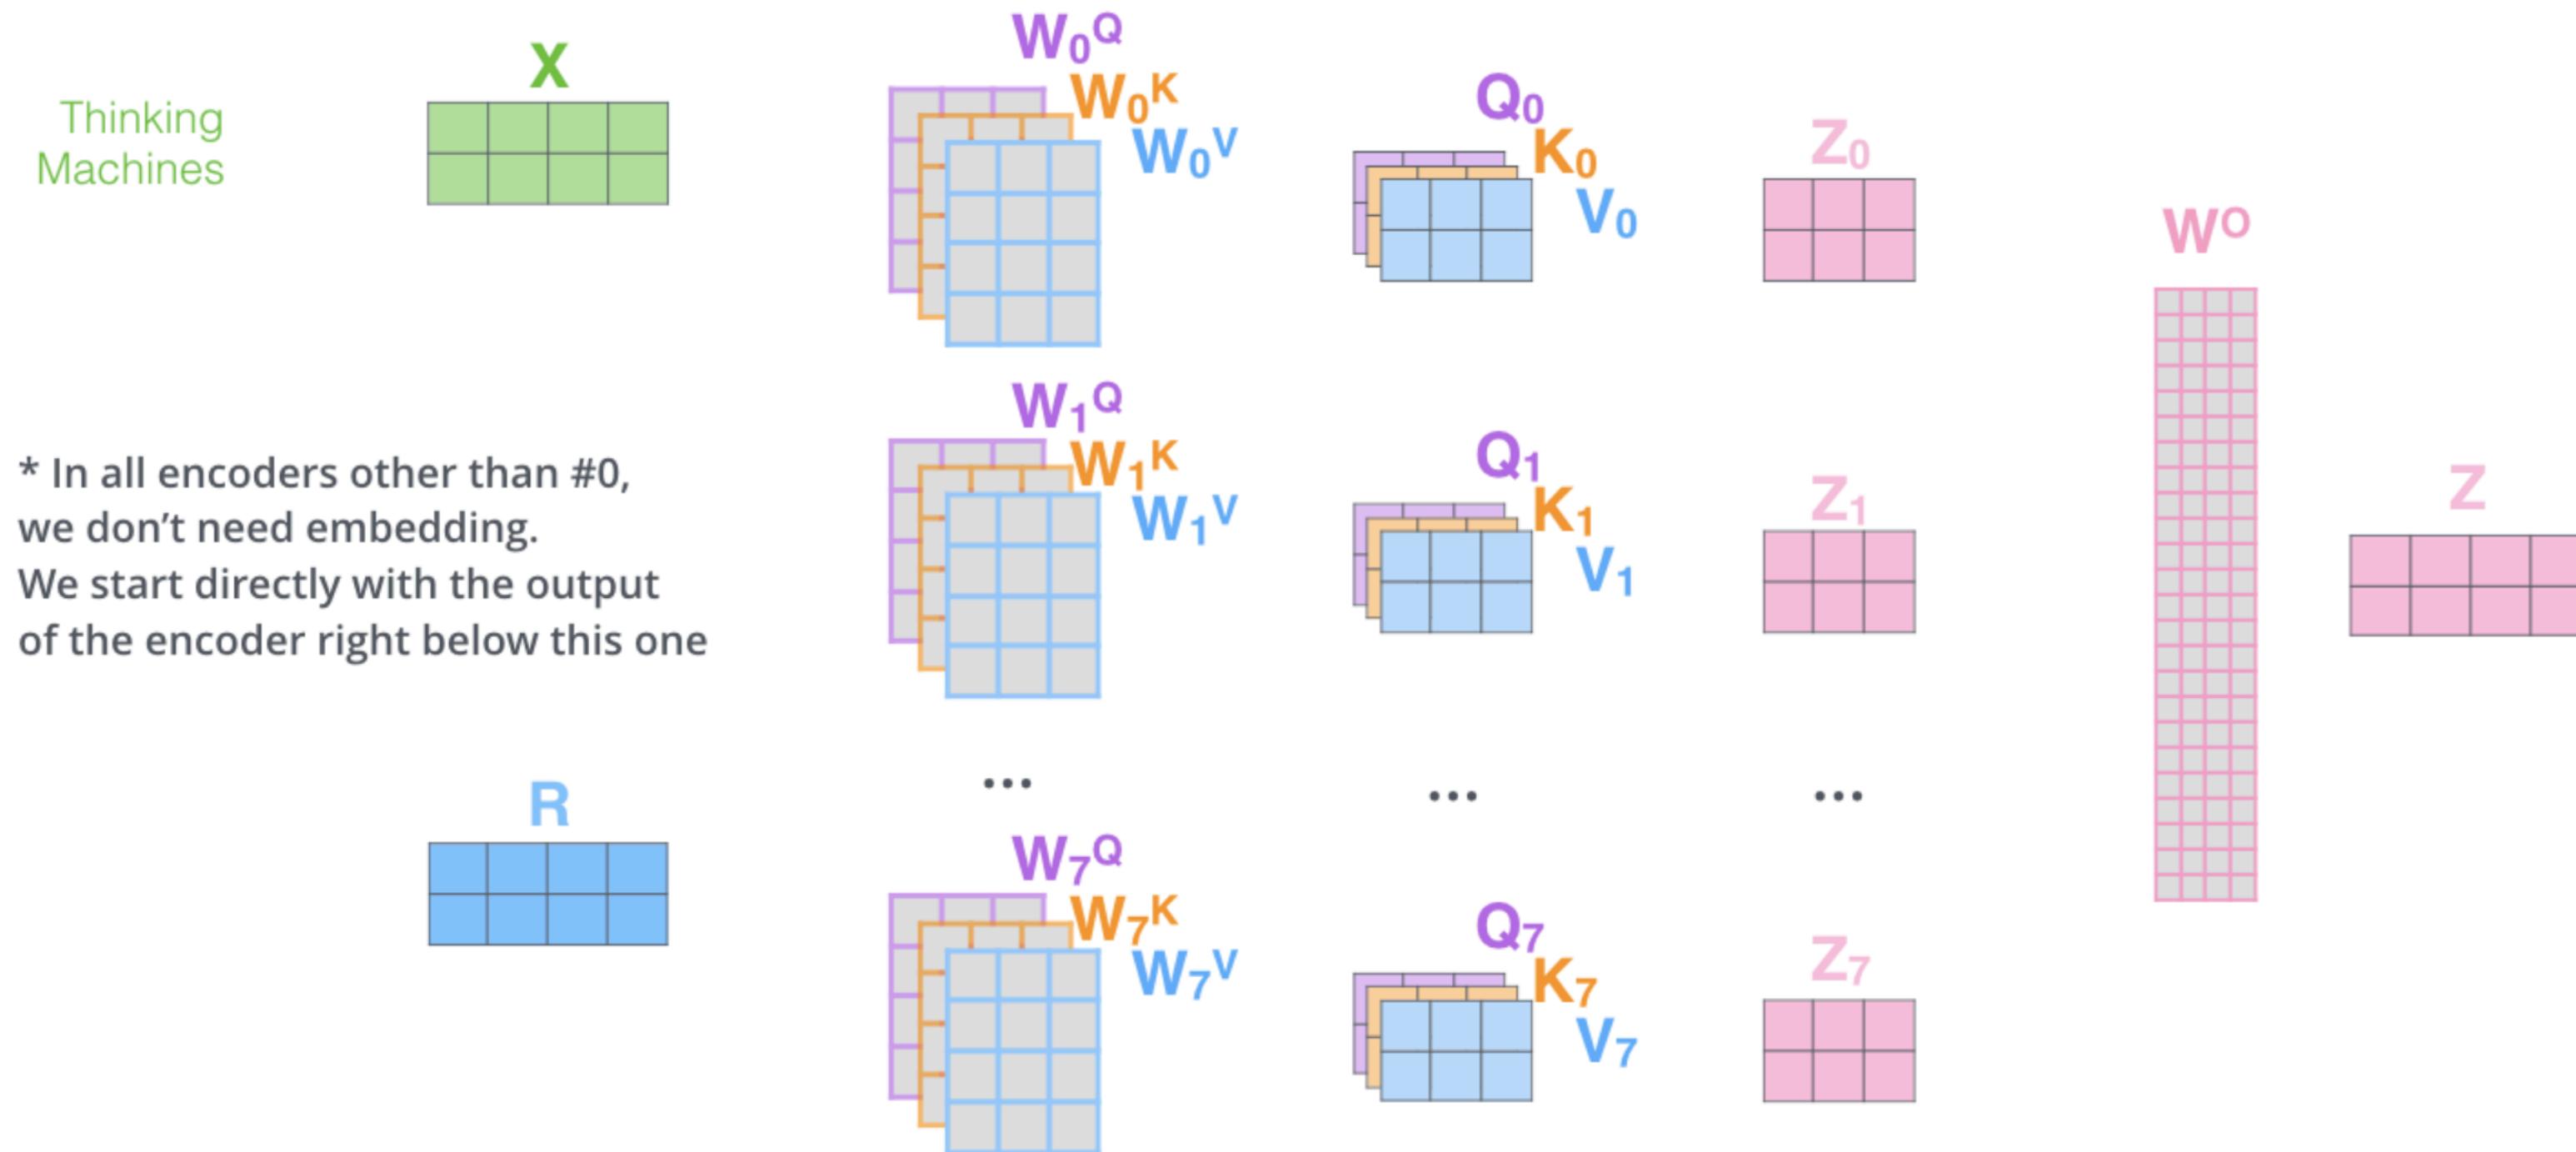

3) The result would be the  $Z$  matrix that captures information from all the attention heads. We can send this forward to the FFNN

$$= \begin{matrix} Z \\ \hline \end{matrix}$$

# Transformer

## Overall architecture

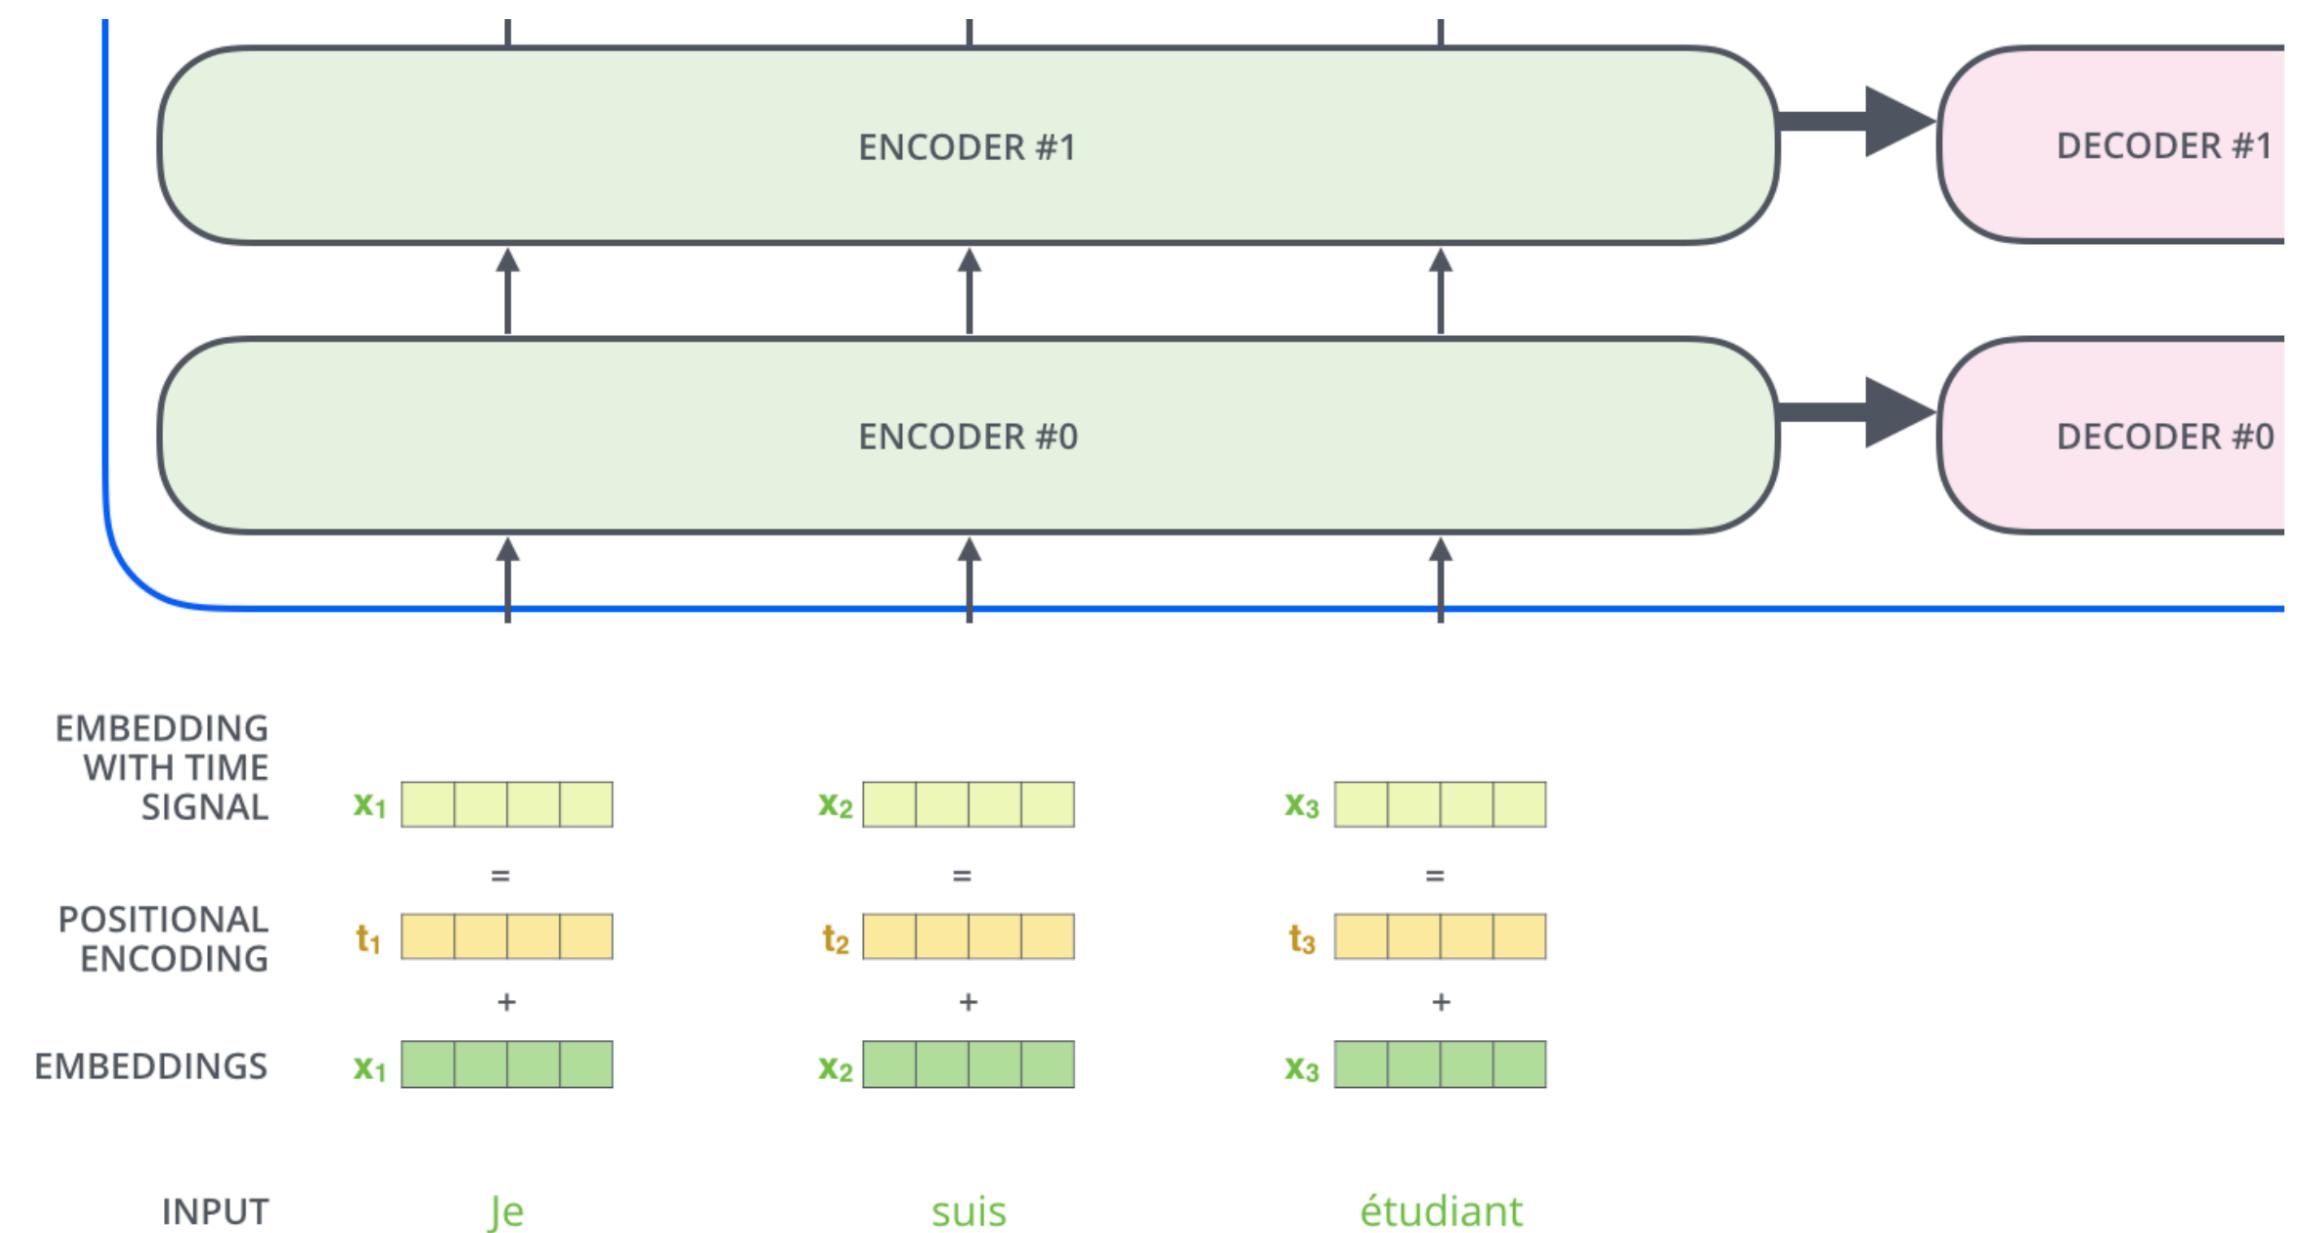

- 1) This is our input sentence\*  
Thinking Machines
- 2) We embed each word\*  
 $X$
- 3) Split into 8 heads.  
We multiply  $X$  or  $R$  with weight matrices
- 4) Calculate attention using the resulting  $Q/K/V$  matrices
- 5) Concatenate the resulting  $Z$  matrices, then multiply with weight matrix  $W^O$  to produce the output of the layer

# Transformer

## Sinusoidal Position Encoding

- The above architecture **ignores** the sequential information
- Add a **positional encoding vector** to each  $x_i$  (according to  $i$ )

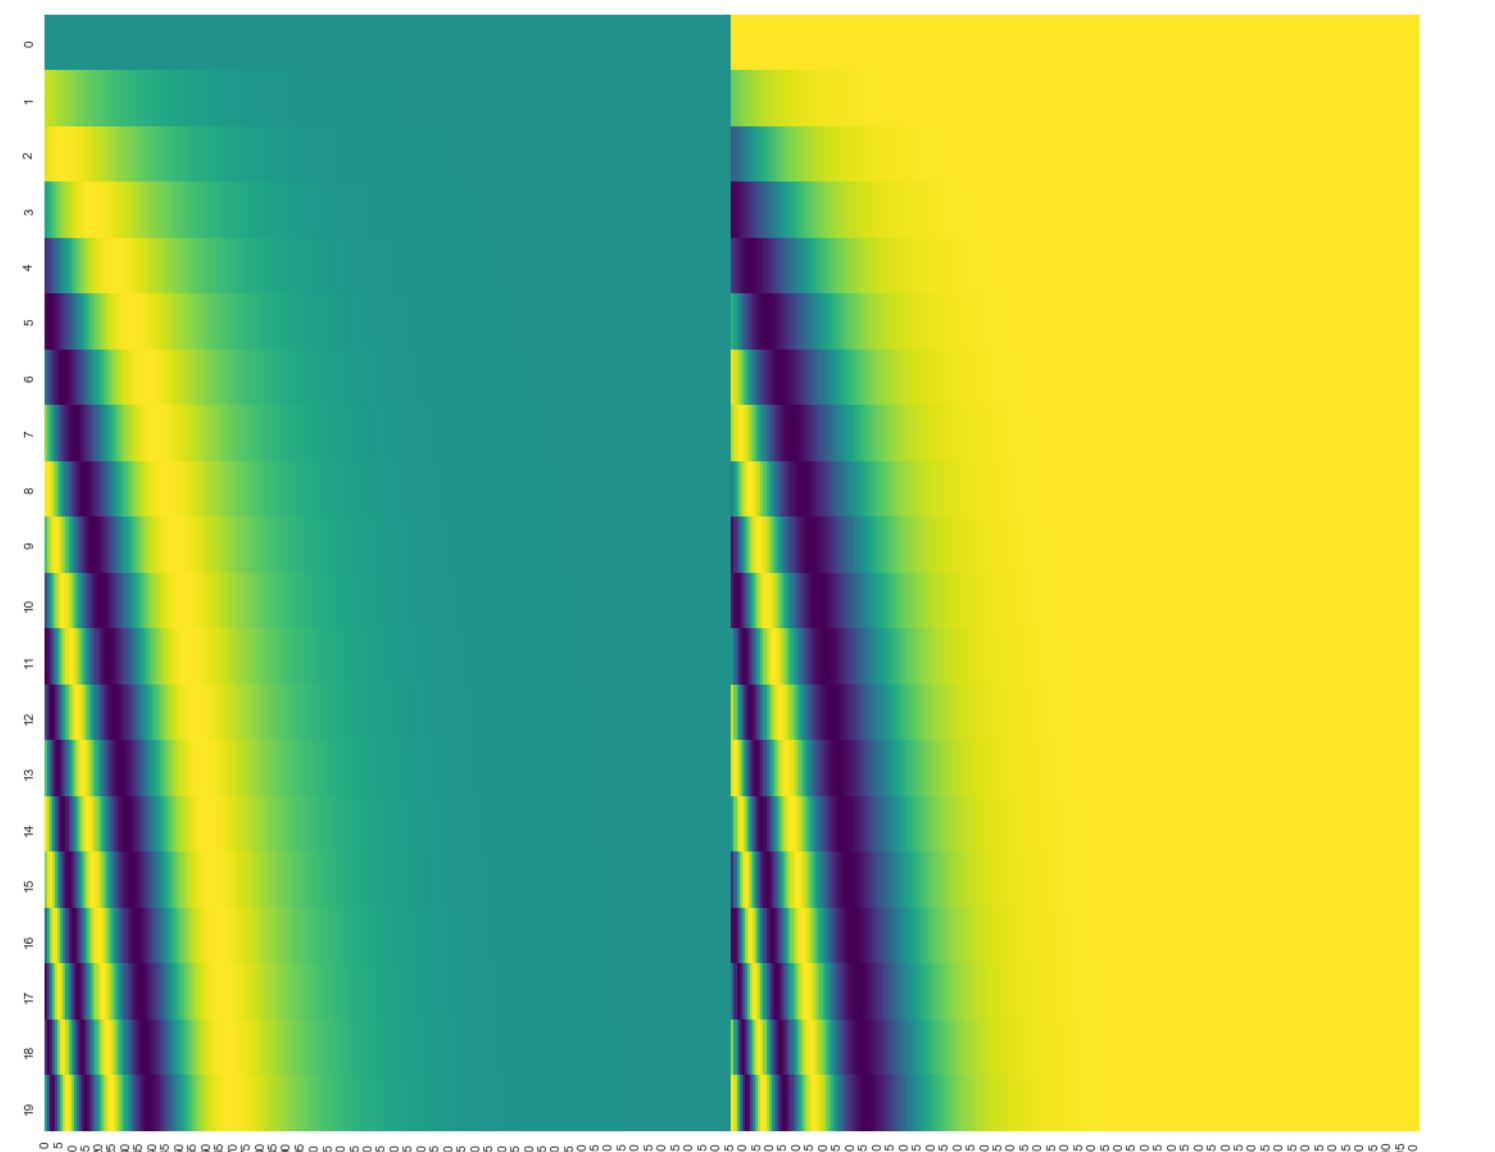

# Transformer Positional Embedding

- Sin/cosine functions with different wavelengths (used in the original Transformer)

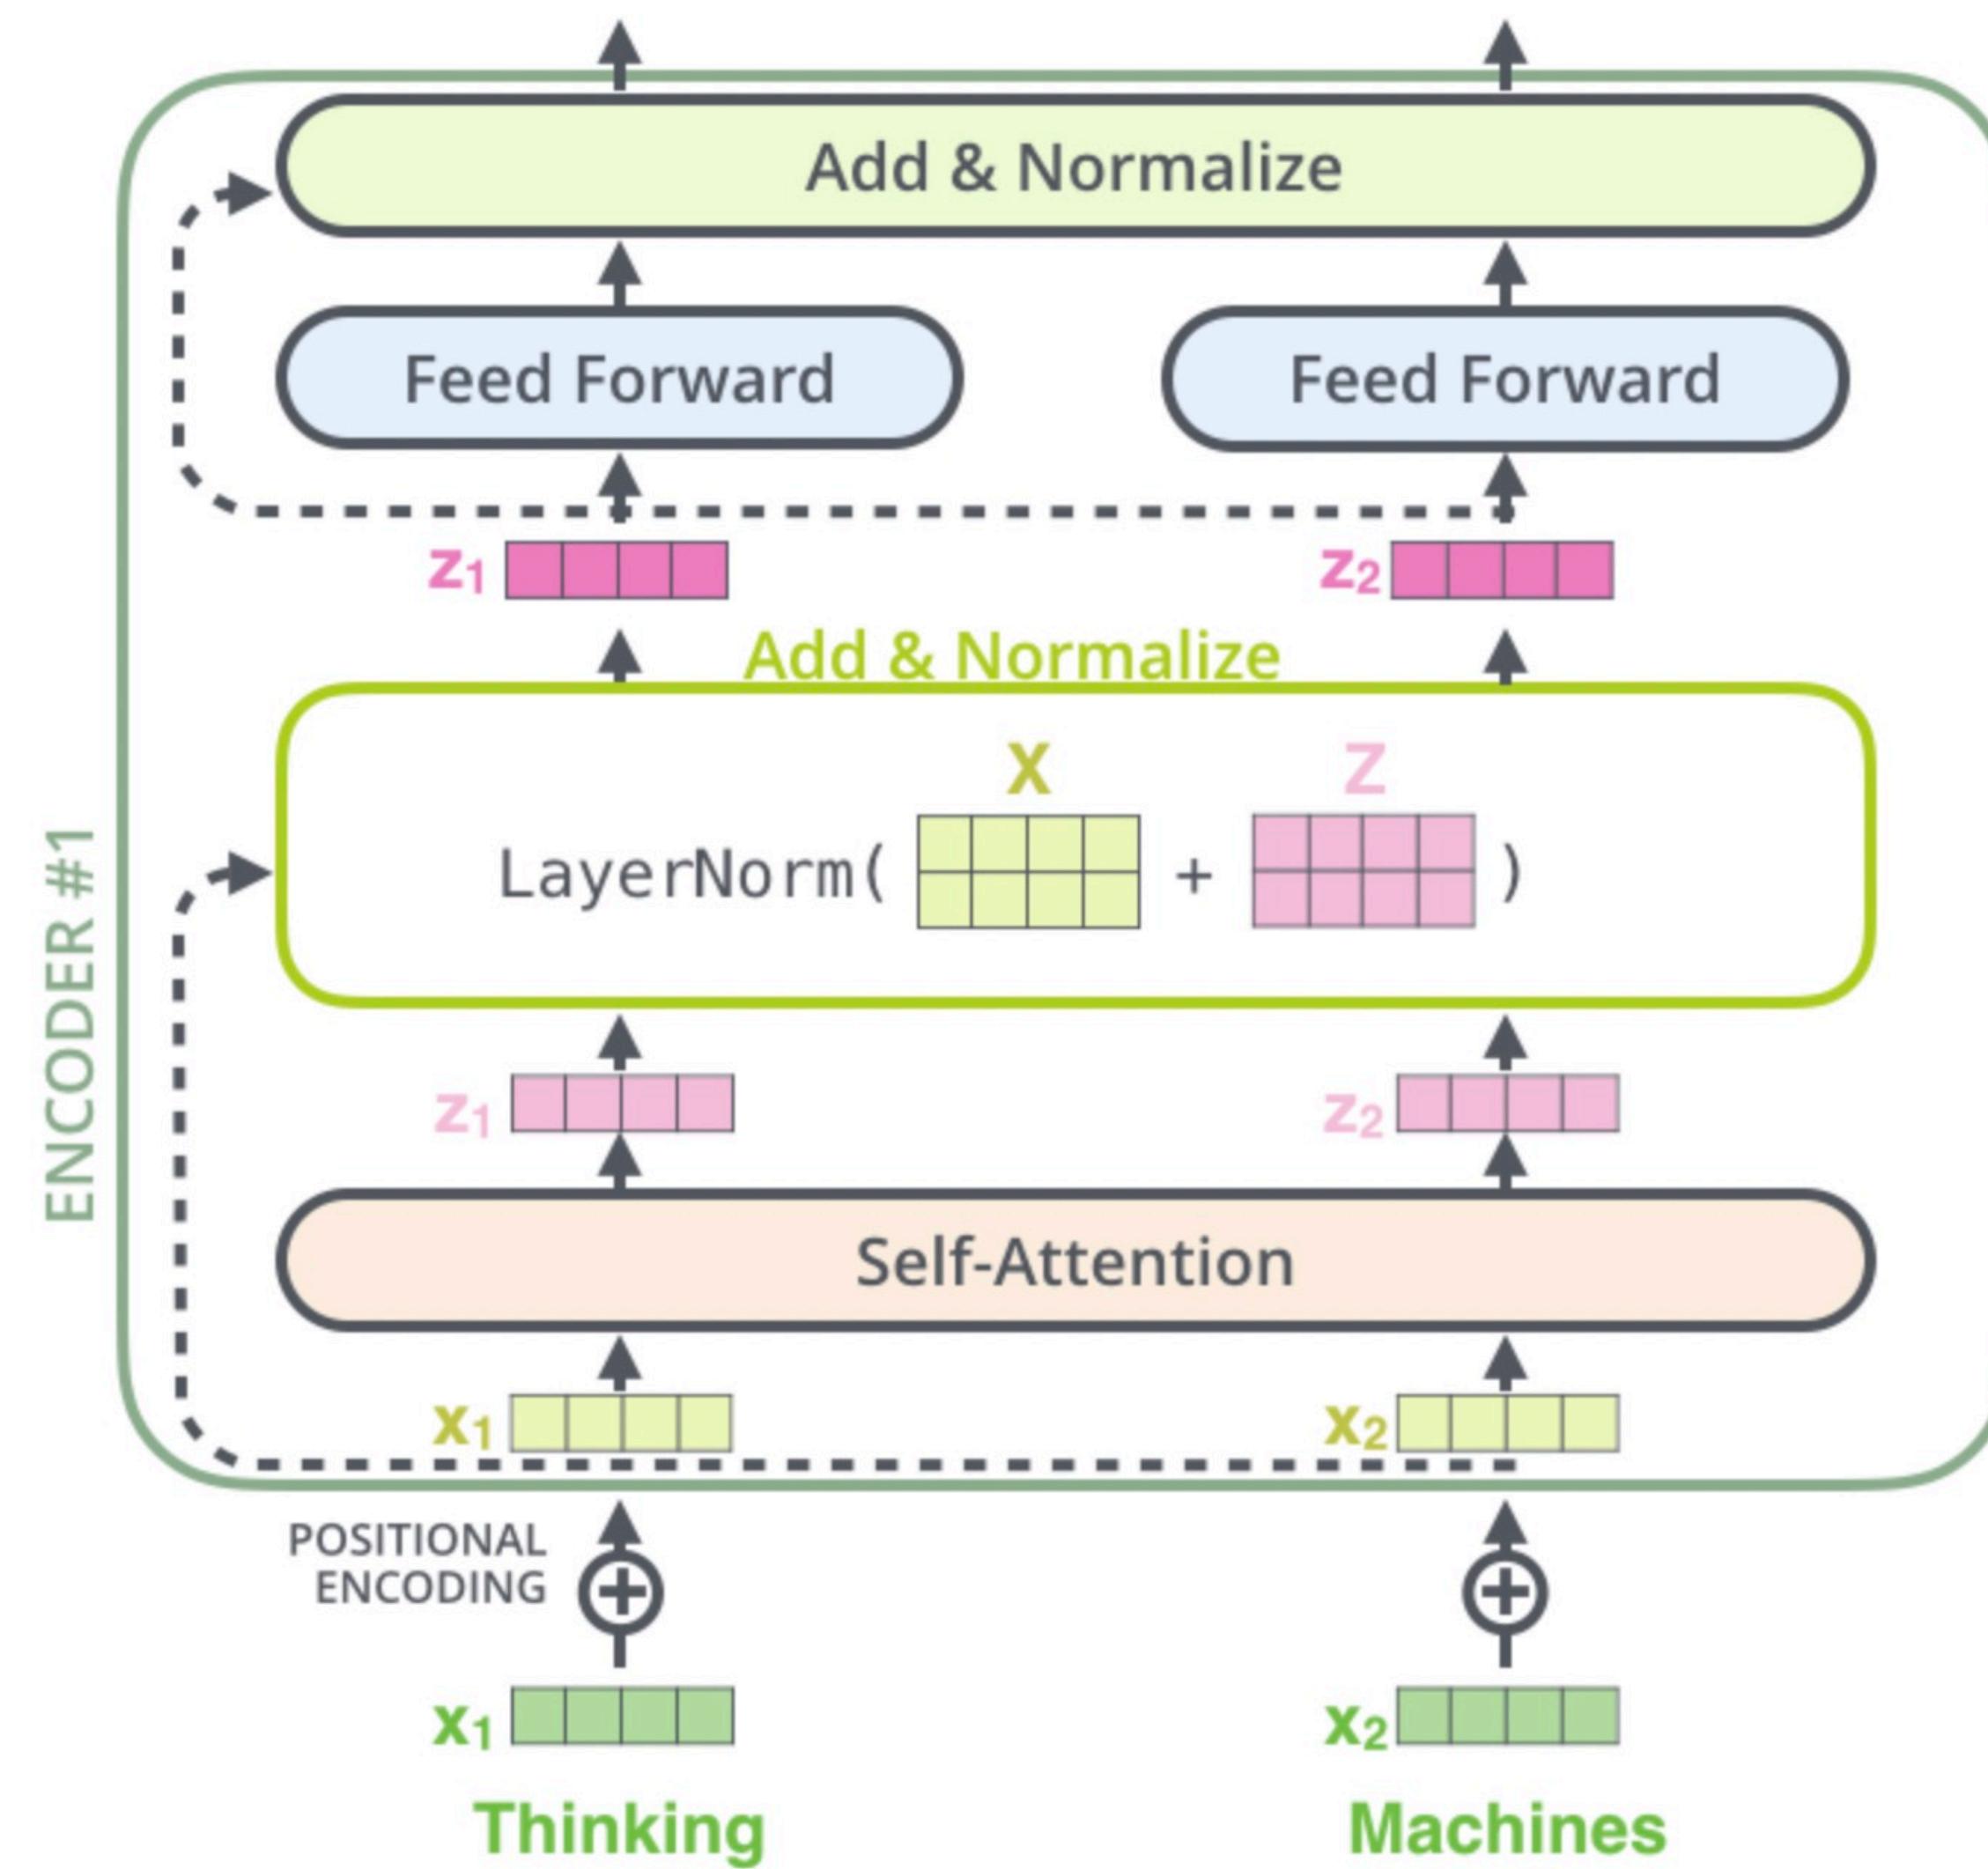

- The jth dimension of ith token  $p_i[j] = \begin{cases} \sin(i \cdot c^{\frac{j}{d}}) & \text{if } j \text{ is even} \\ \cos(i \cdot c^{\frac{j-1}{d}}) & \text{if } j \text{ is odd} \end{cases}$

- smooth, parameter-free, inductive

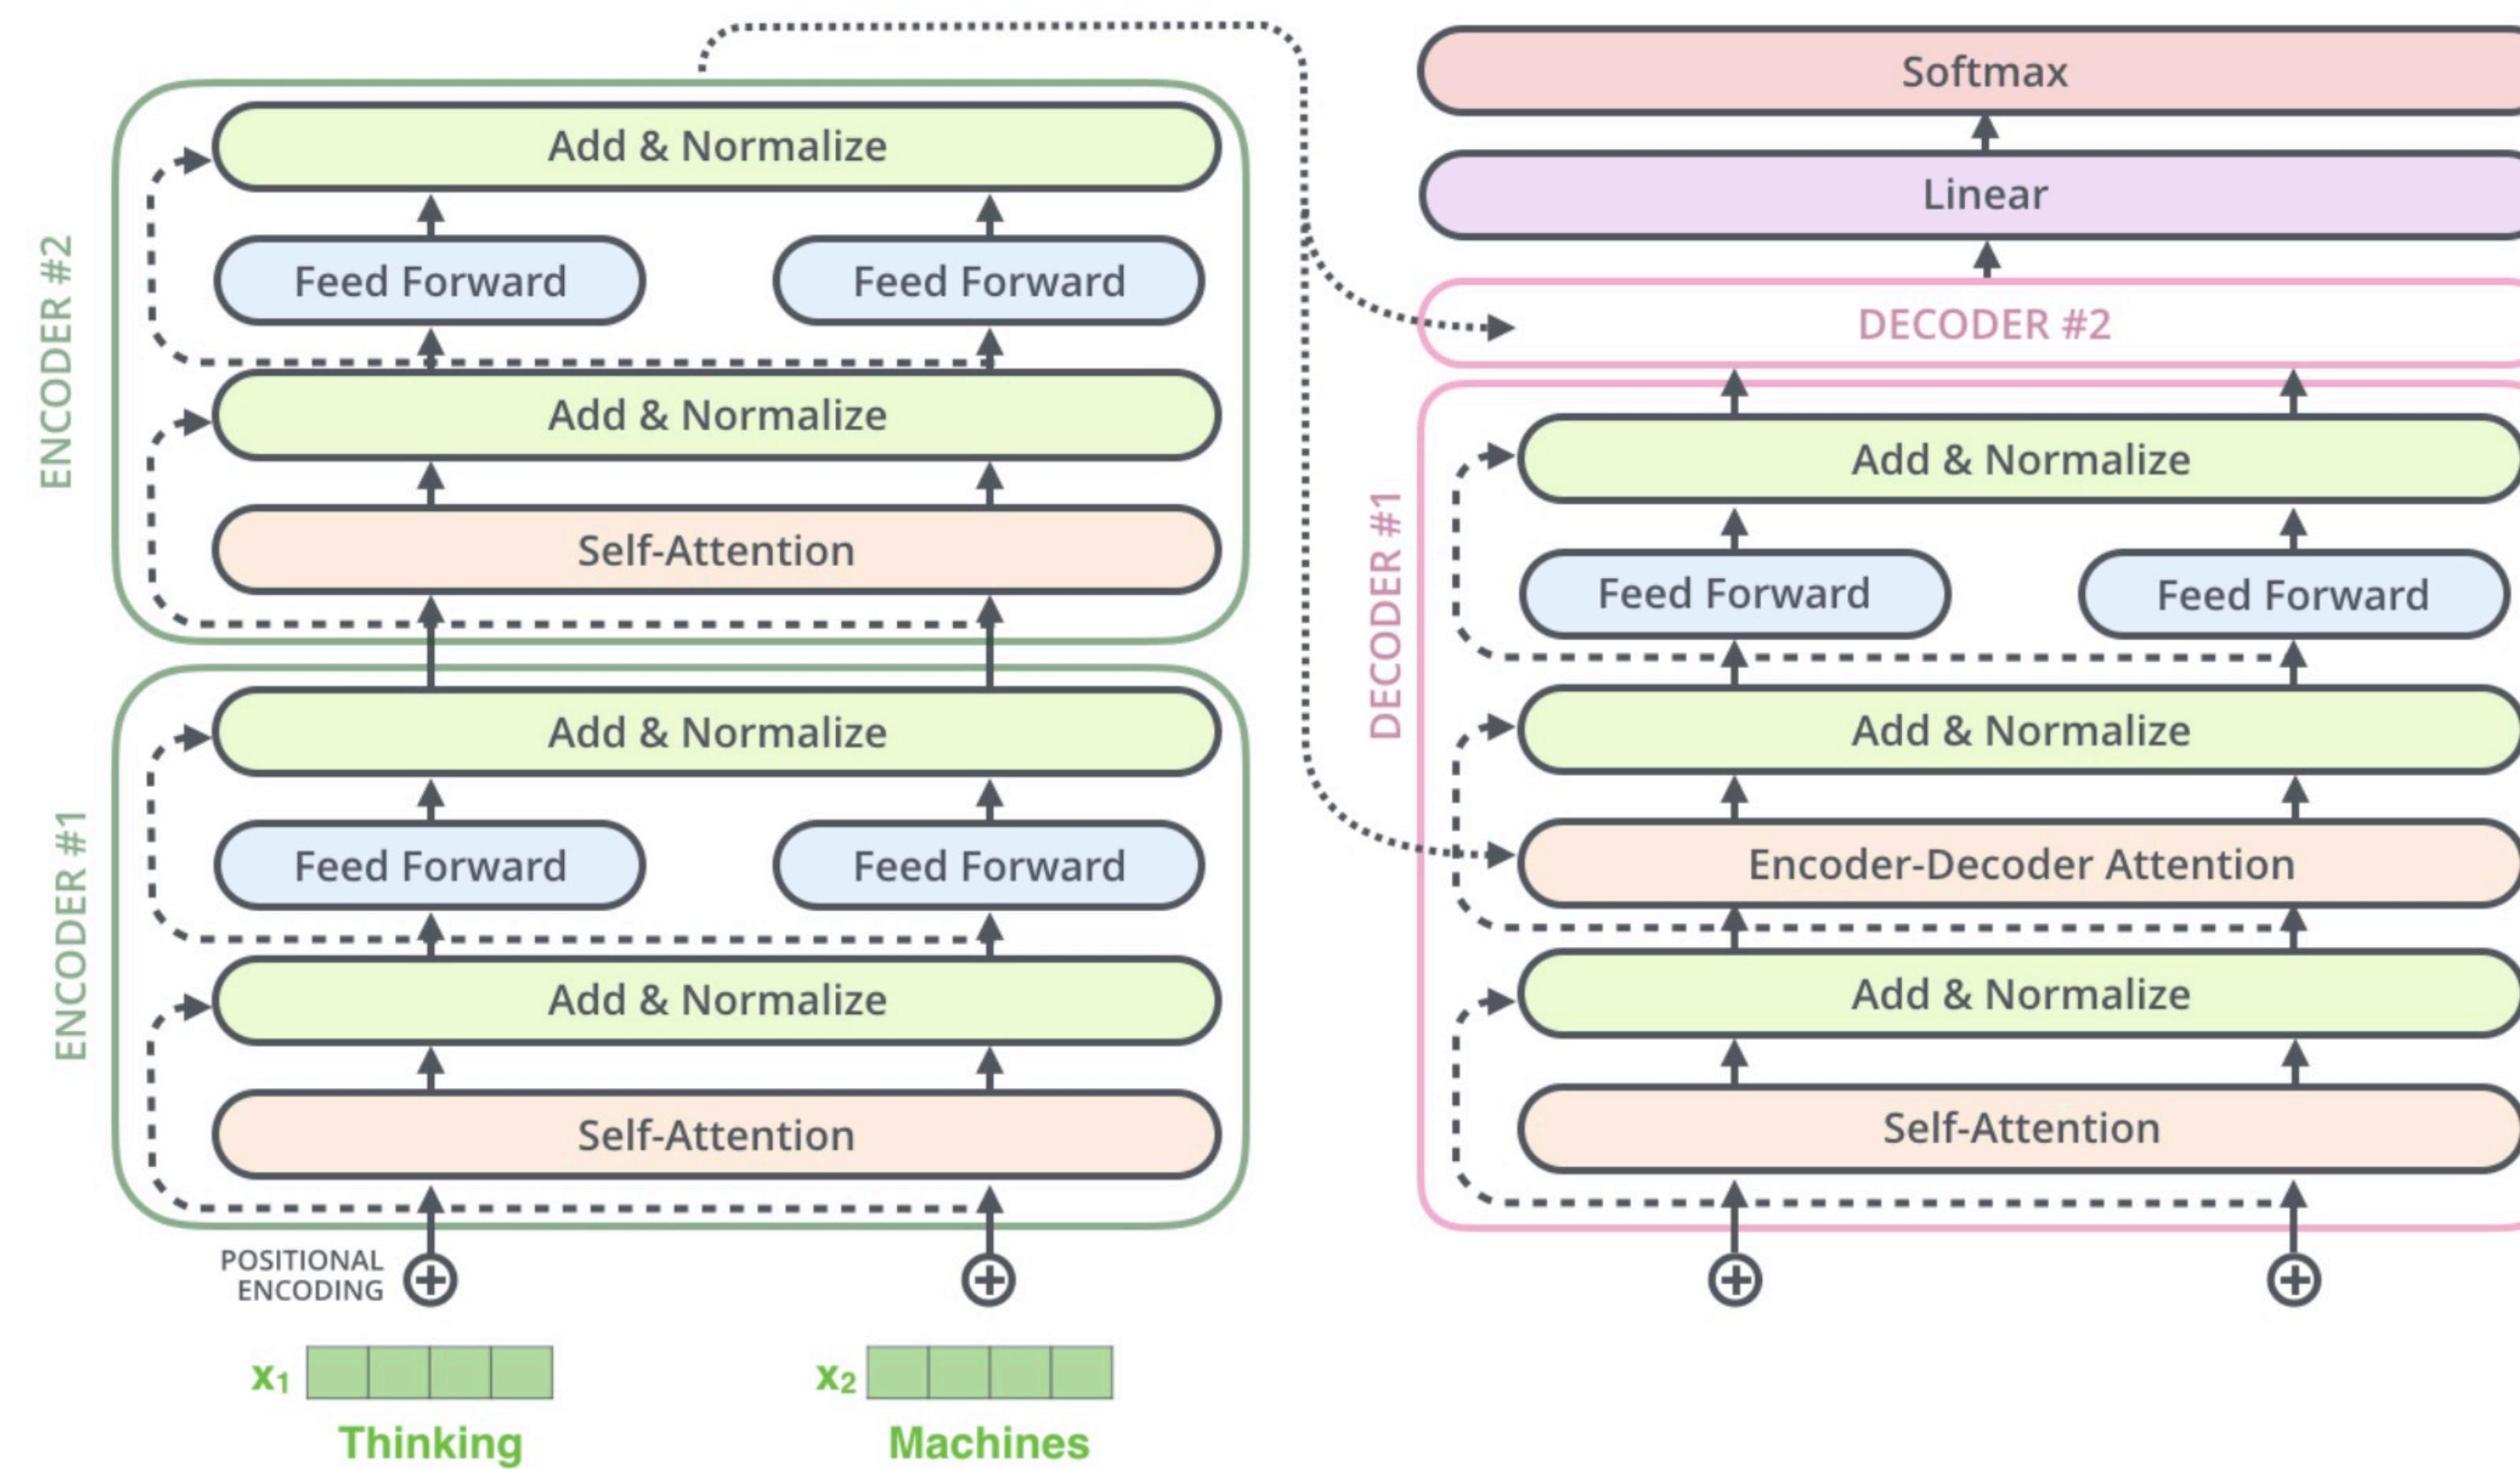

# Transformer

## Residual

# Transformer

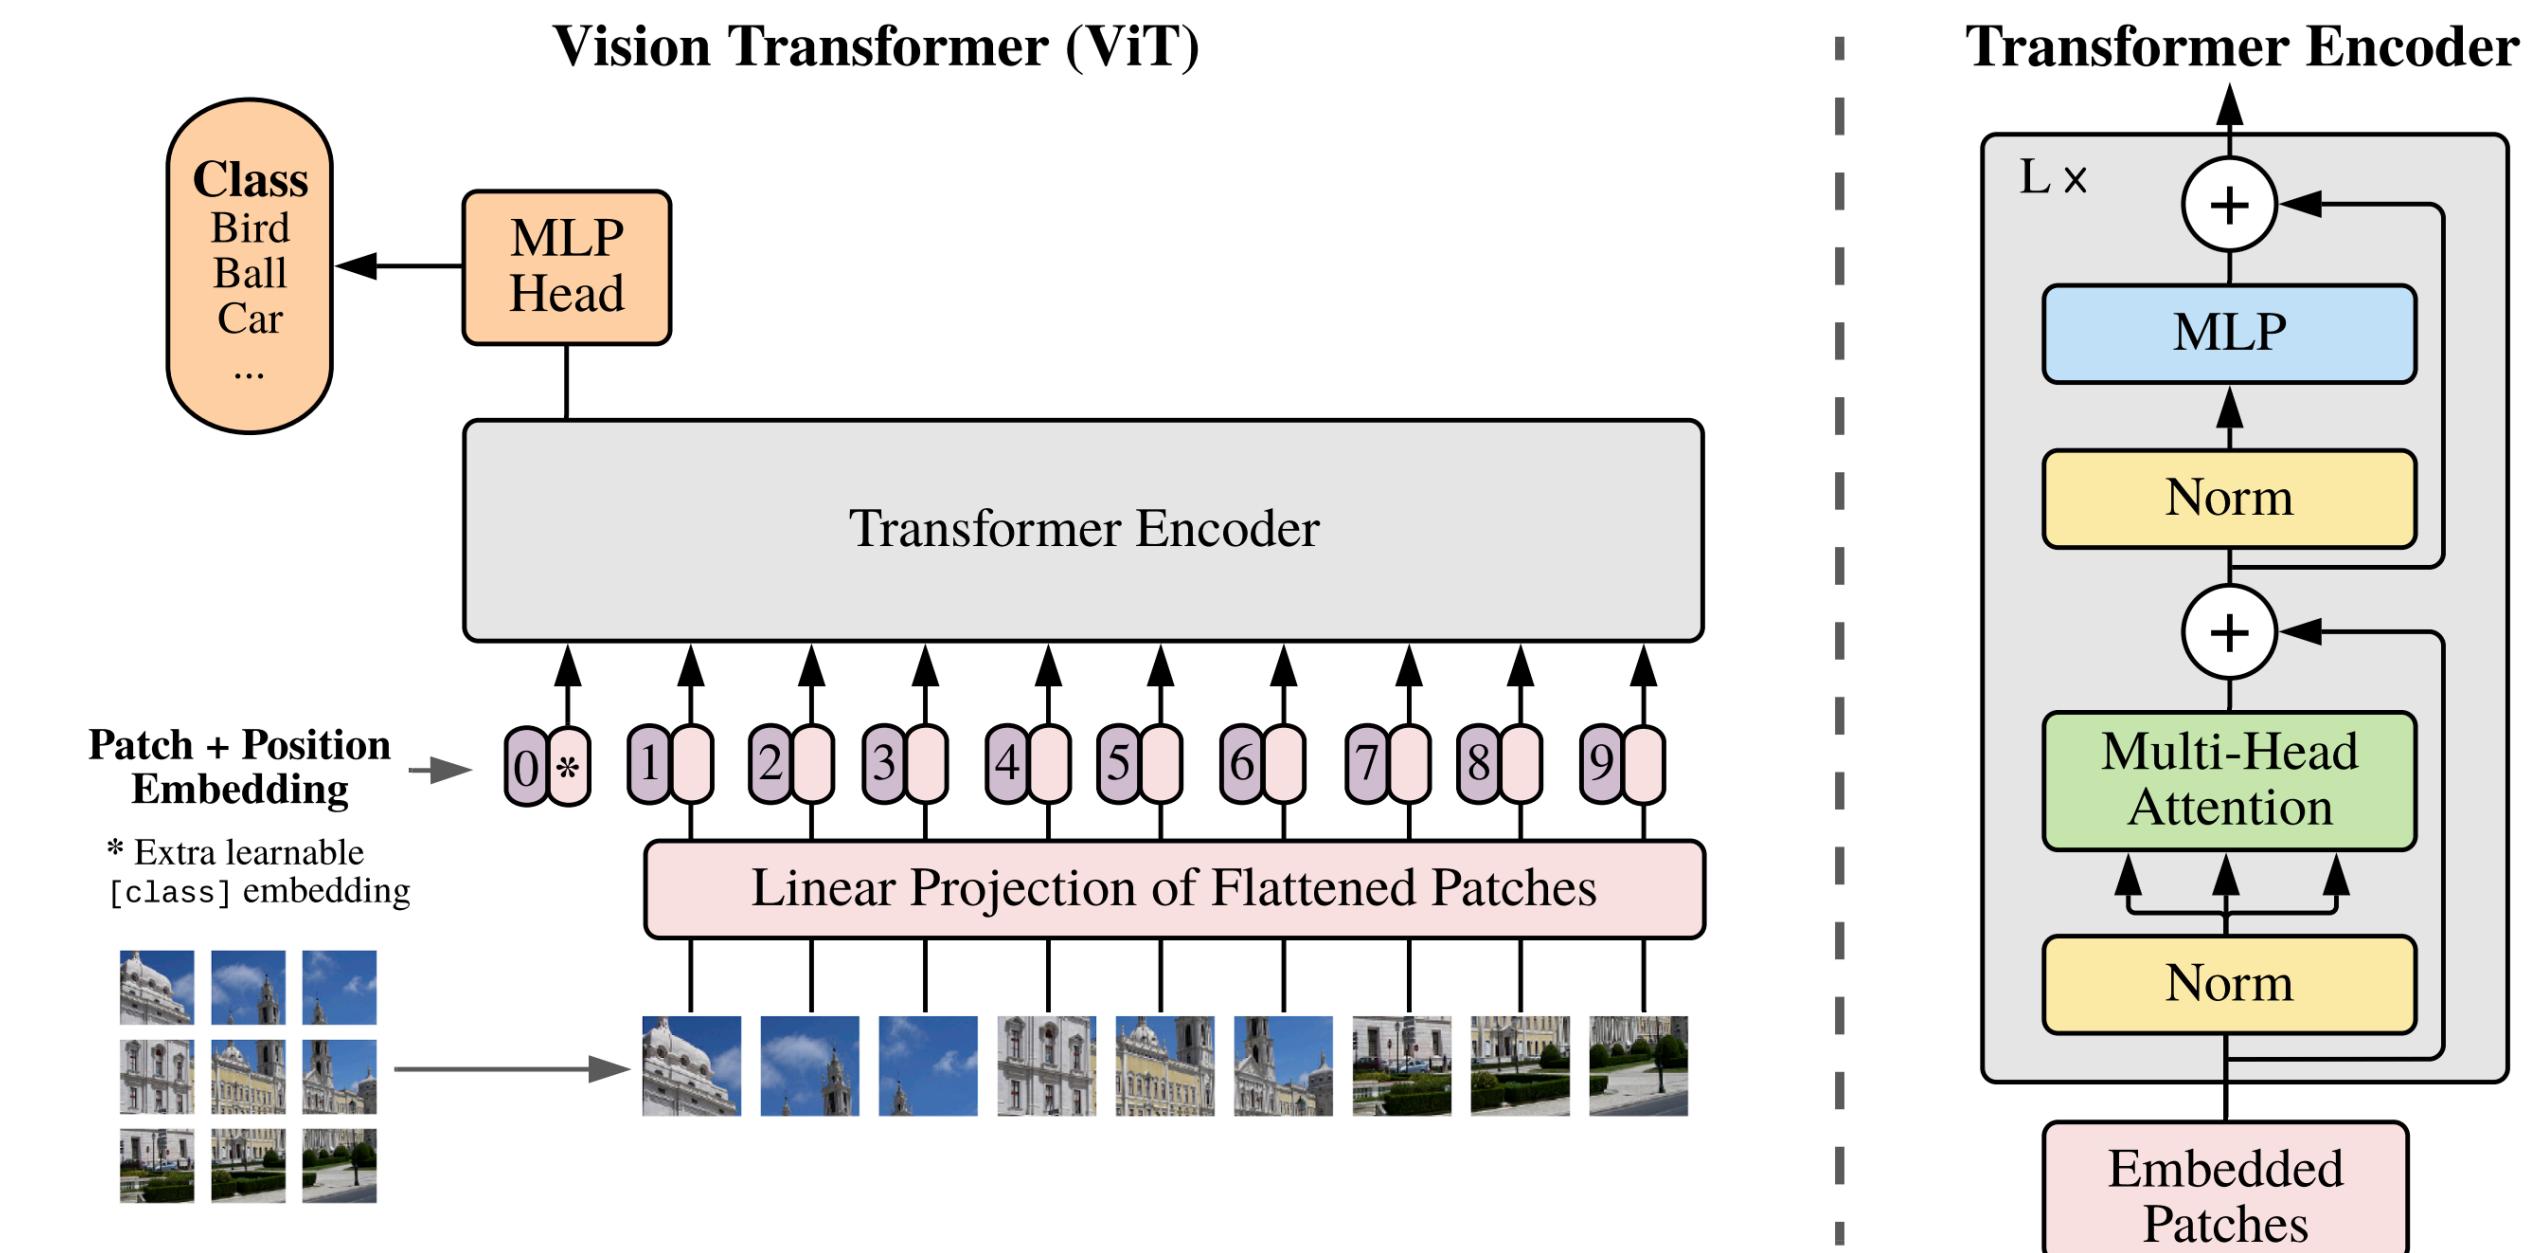

## Whole framework

# Vision Transformer (ViT)

## Vision Transformer (ViT)

- Partition input image into  $K \times K$  patches
- A linear projection to transform each patch to feature (no convolution)
- Pass tokens into Transformer

# Vision Transformer (ViT)

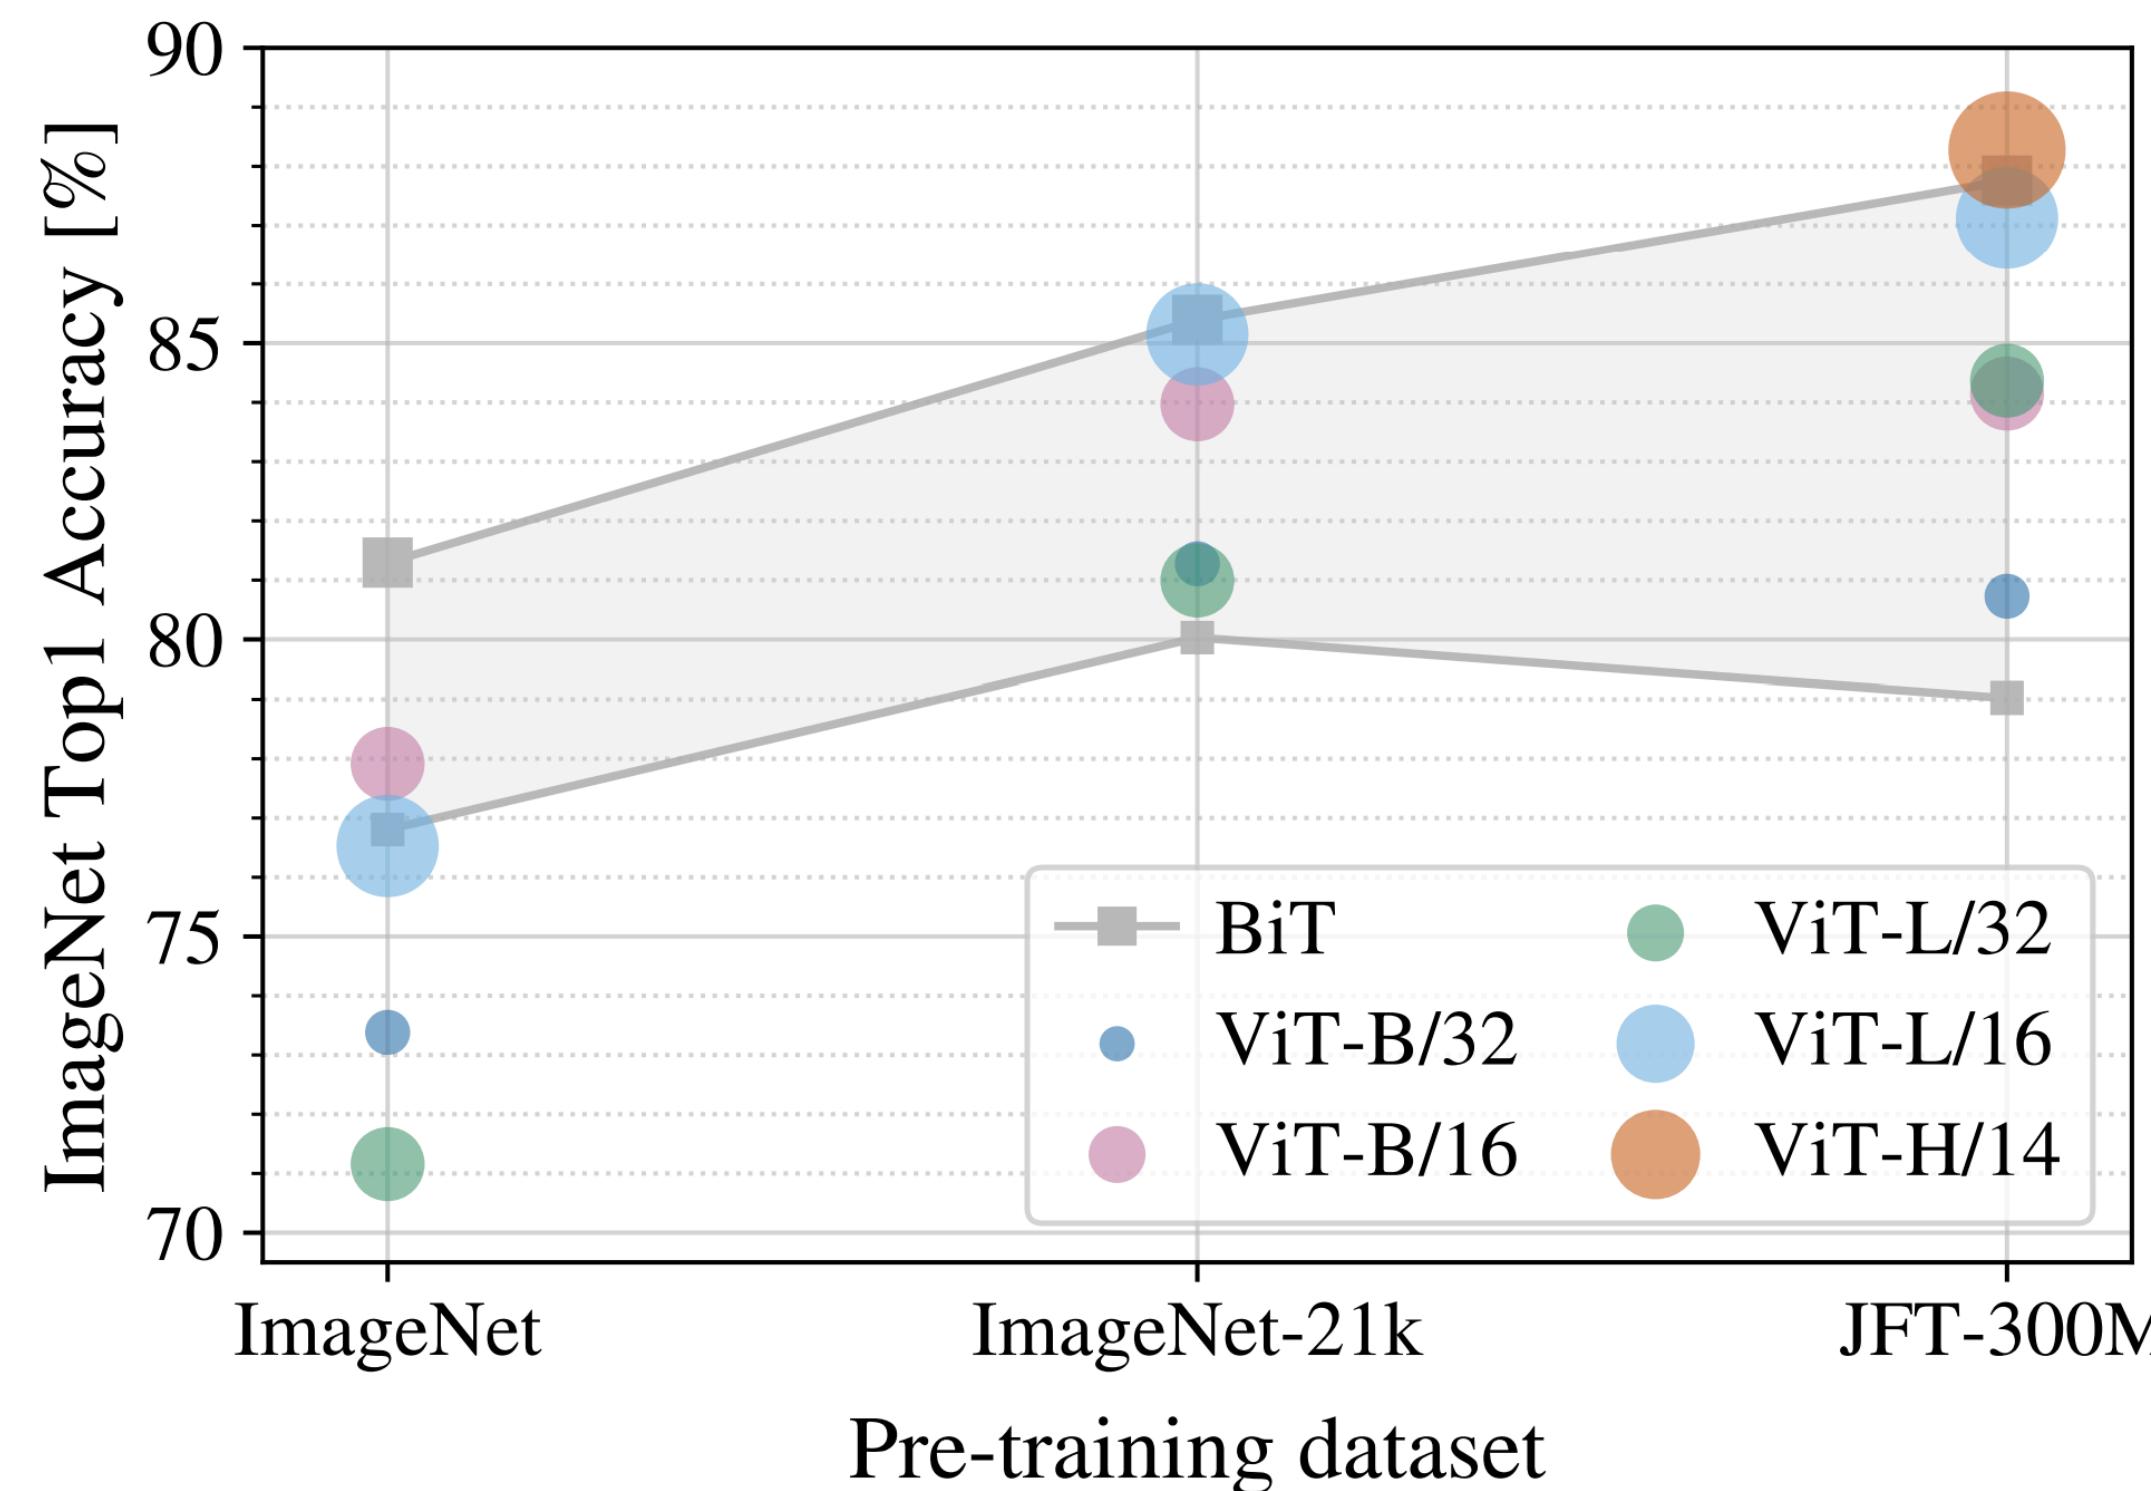

## Vision Transformer (ViT)

- Patches are non-overlapping in the original ViT
- $N \times N$  image  $\Rightarrow (N/K)^2$  tokens
- Smaller patch size  $\Rightarrow$  more input tokens
  - Higher computation (memory) cost, (usually) higher accuracy
- Use 1D (learnable) positional embedding
- Inference with higher resolution:
  - Keep the same patch size, which leads to longer sequence
  - Interpolation for positional embedding

# Vision Transformer (ViT)

## ViT Performance

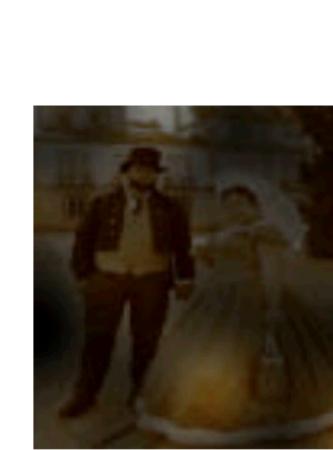

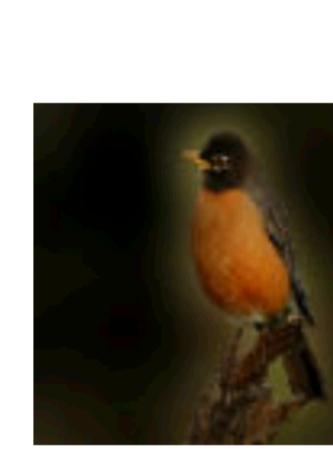

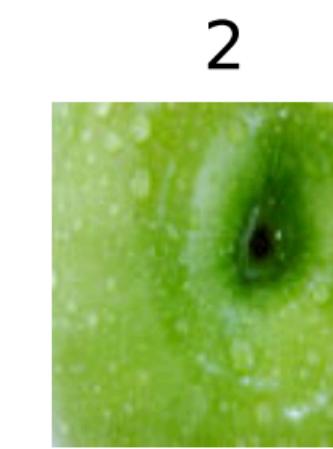

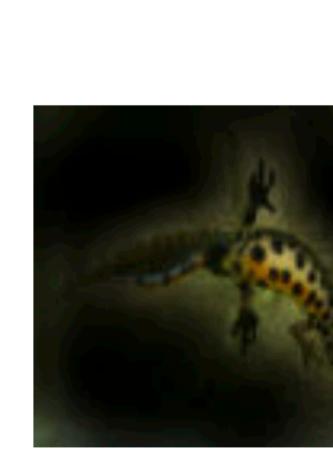

- ViT outperforms CNN with large pretraining

# Vision Transformer (ViT)

## ViT Performance

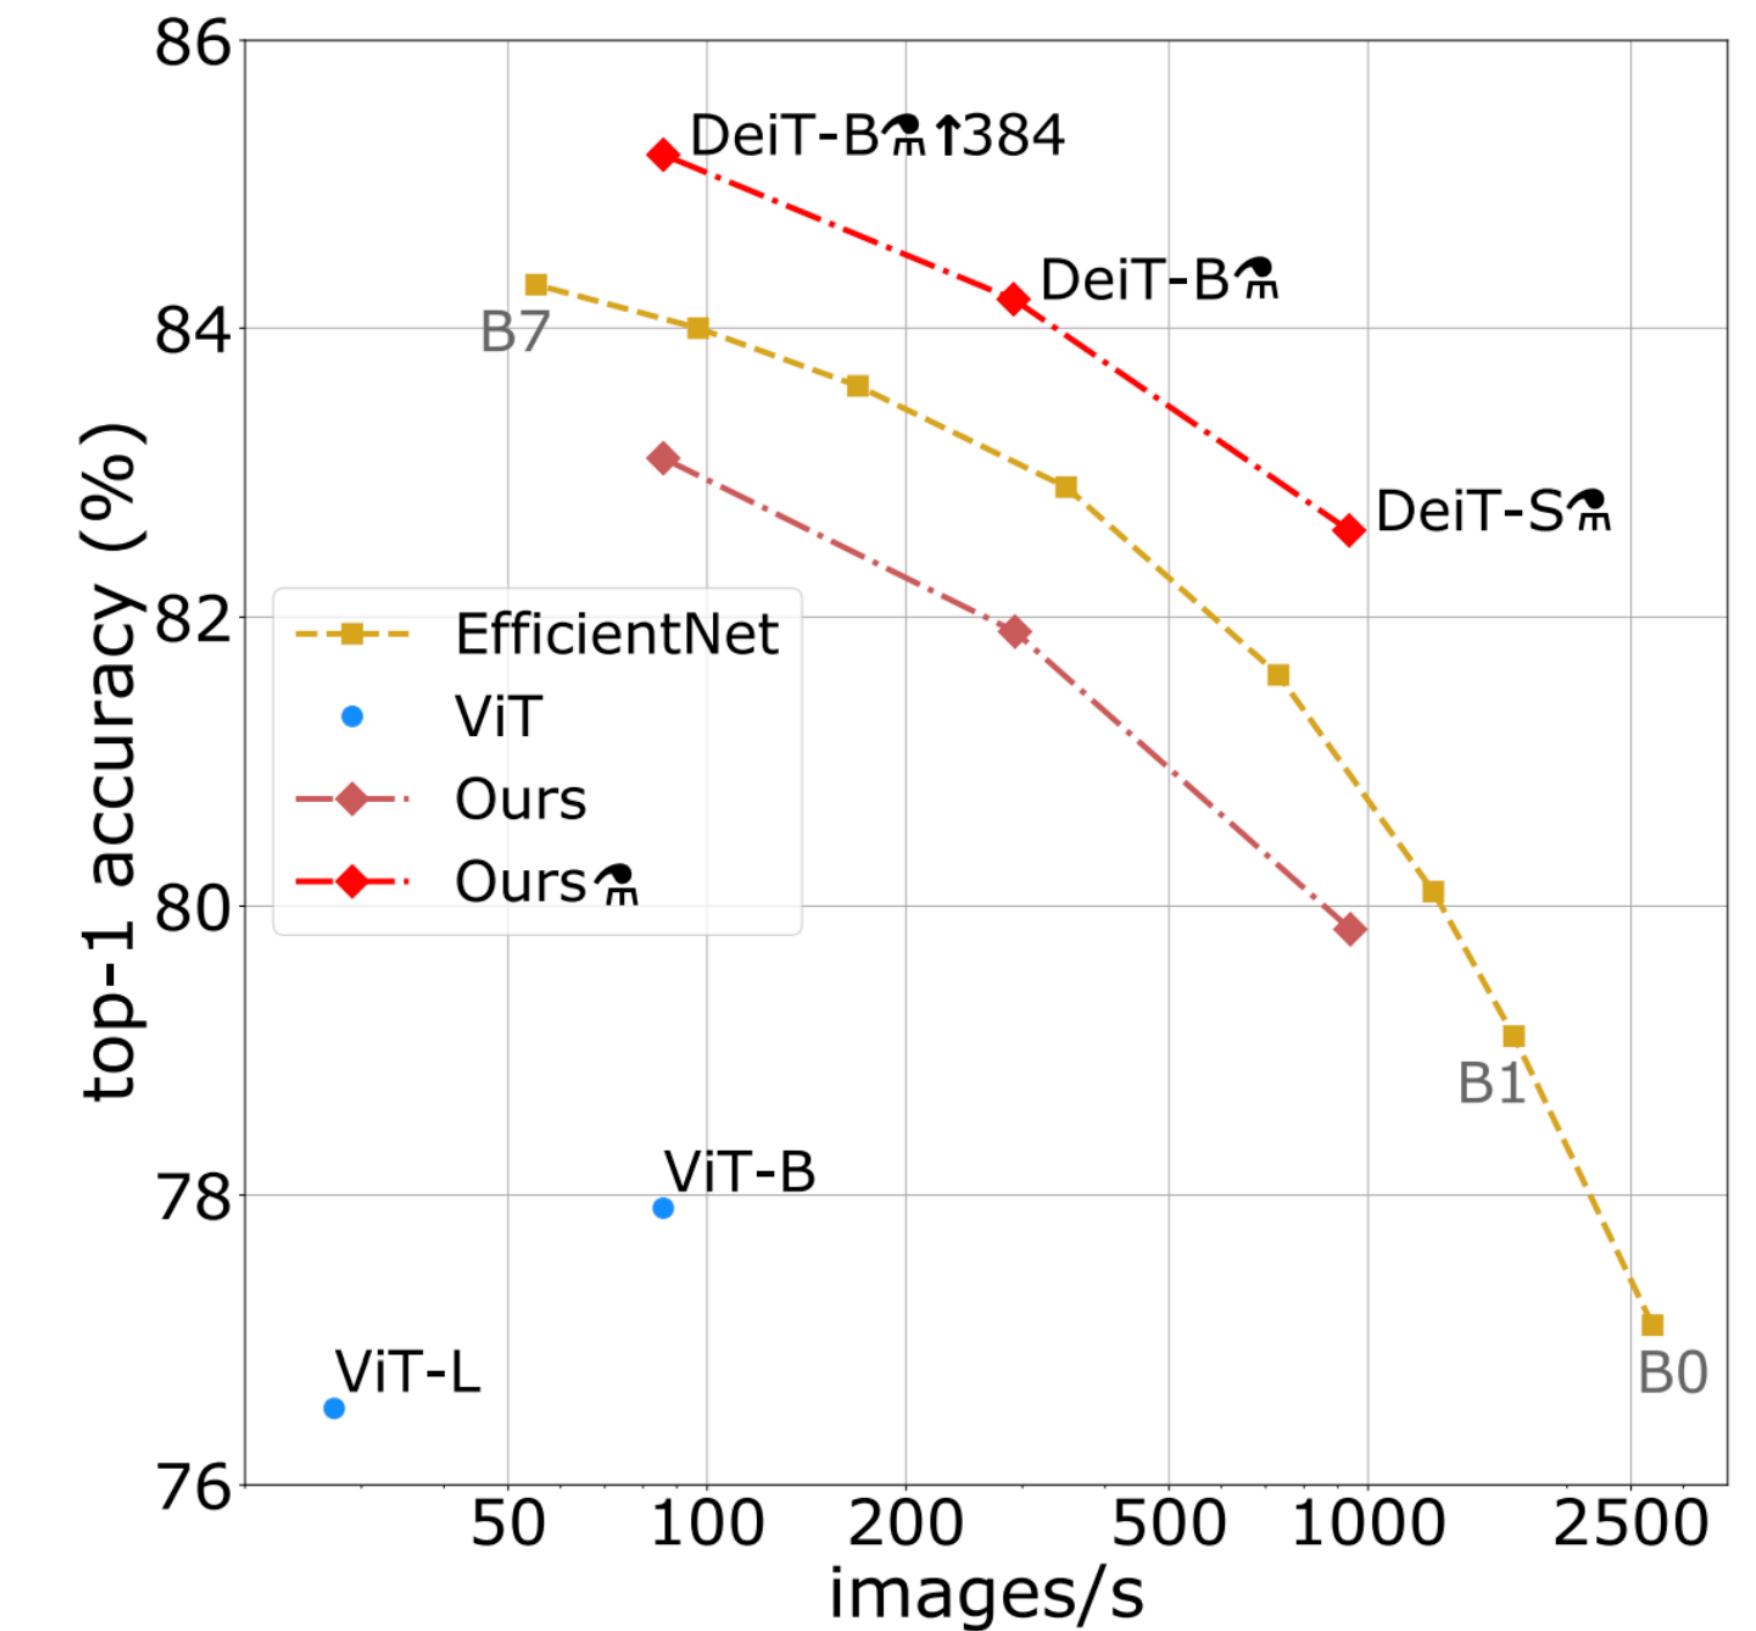

- Attention maps of ViT (to input)

# Vision Transformer (ViT)

## ViT v.s. ResNet

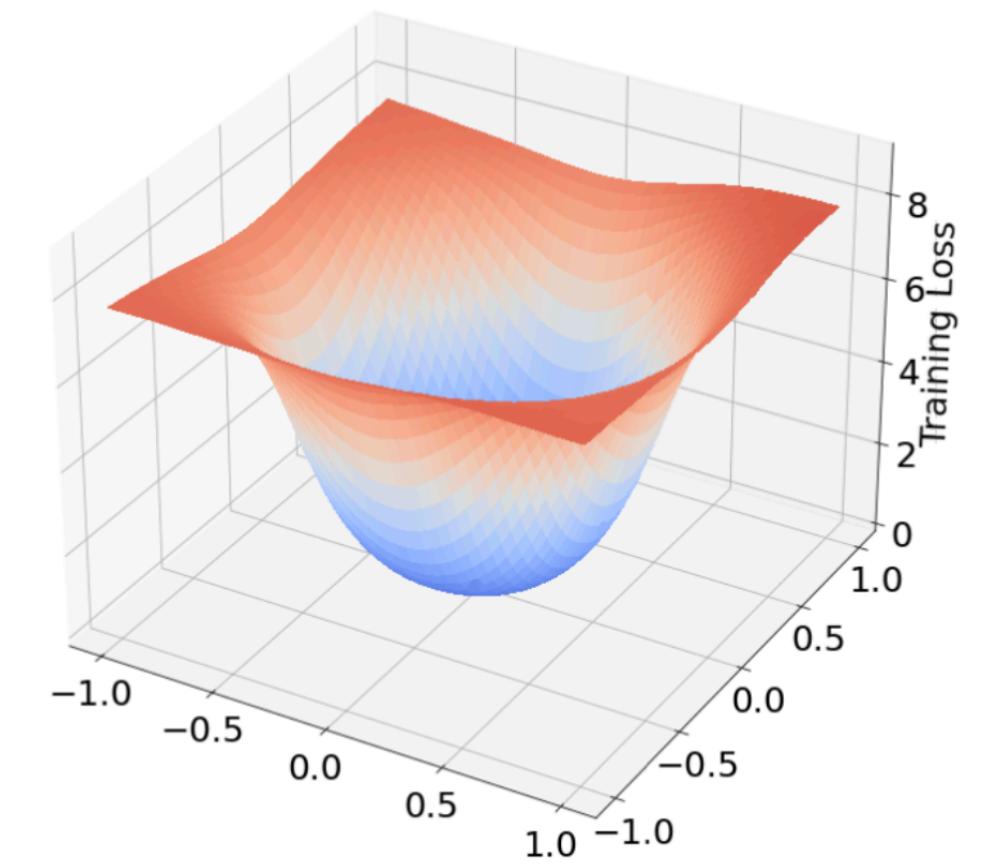

- Can ViT outperform ResNet on ImageNet without pretraining?
- DeiT (Touvron et al., 2021):
  - Use very strong data augmentation
  - Use a ResNet teacher and distill to ViT

# Vision Transformer (ViT)

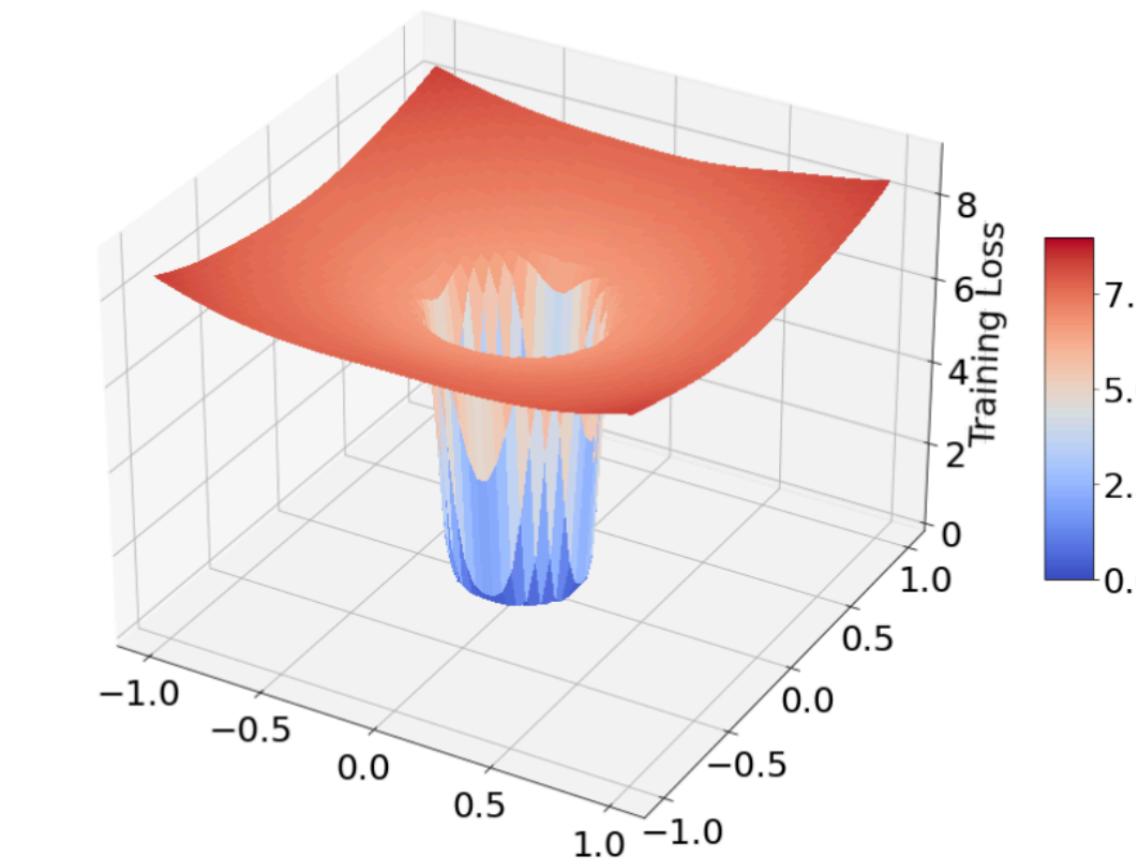

## ViT v.s. ResNet

- ViT tends to converge to sharper regions than ResNet

(a) ResNet

Leading eigenvalue of  
Hessian: **179.8**

(b) ViT

Leading eigenvalue of  
Hessian: **738.8**

# Vision Transformer (ViT)

“Sharpness” is related to generalization

- Testing can be viewed as a slightly perturbed training distribution
- Sharp minimum  $\Rightarrow$  performance degrades significantly from training to testing

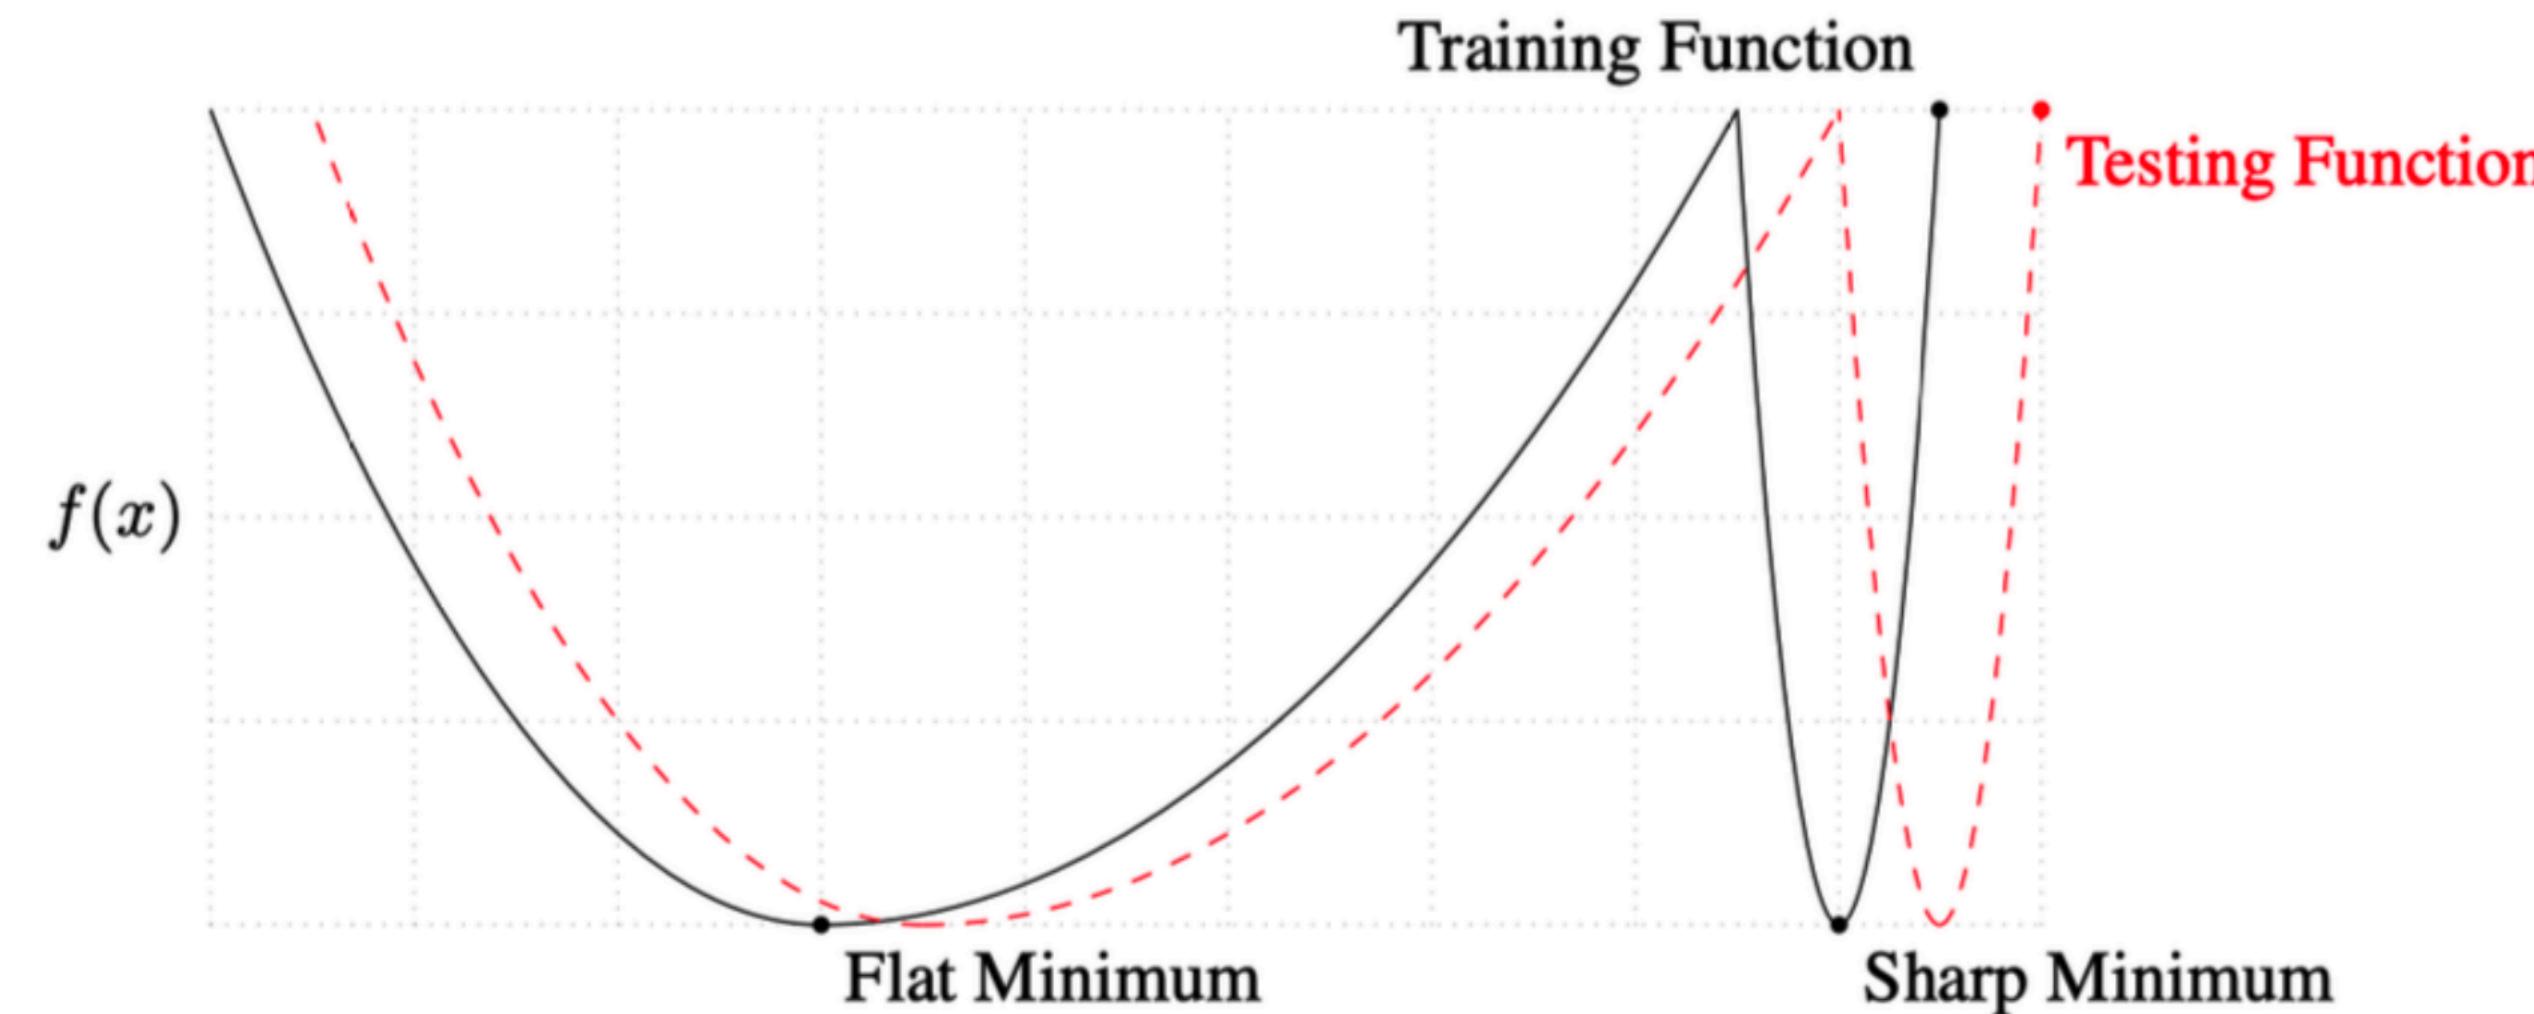

Figure from (Keskar et al., 2017)

# Vision Transformer (ViT)

## Sharpness Aware Minimization (SAM)

- Optimize the worst-case loss within a small neighborhood

- $\min_w \max_{\|\delta\|_2 \leq \epsilon} L(w + \delta)$

- $\epsilon$  is a small constant (hyper-parameter)

- Use 1-step gradient ascent to approximate inner max:

- $\hat{\delta} = \arg \max_{\|\delta\|_2 \leq \epsilon} L(w) + \nabla L(w)^T \delta = \epsilon \frac{\nabla L(w)}{\|\nabla L(w)\|}$

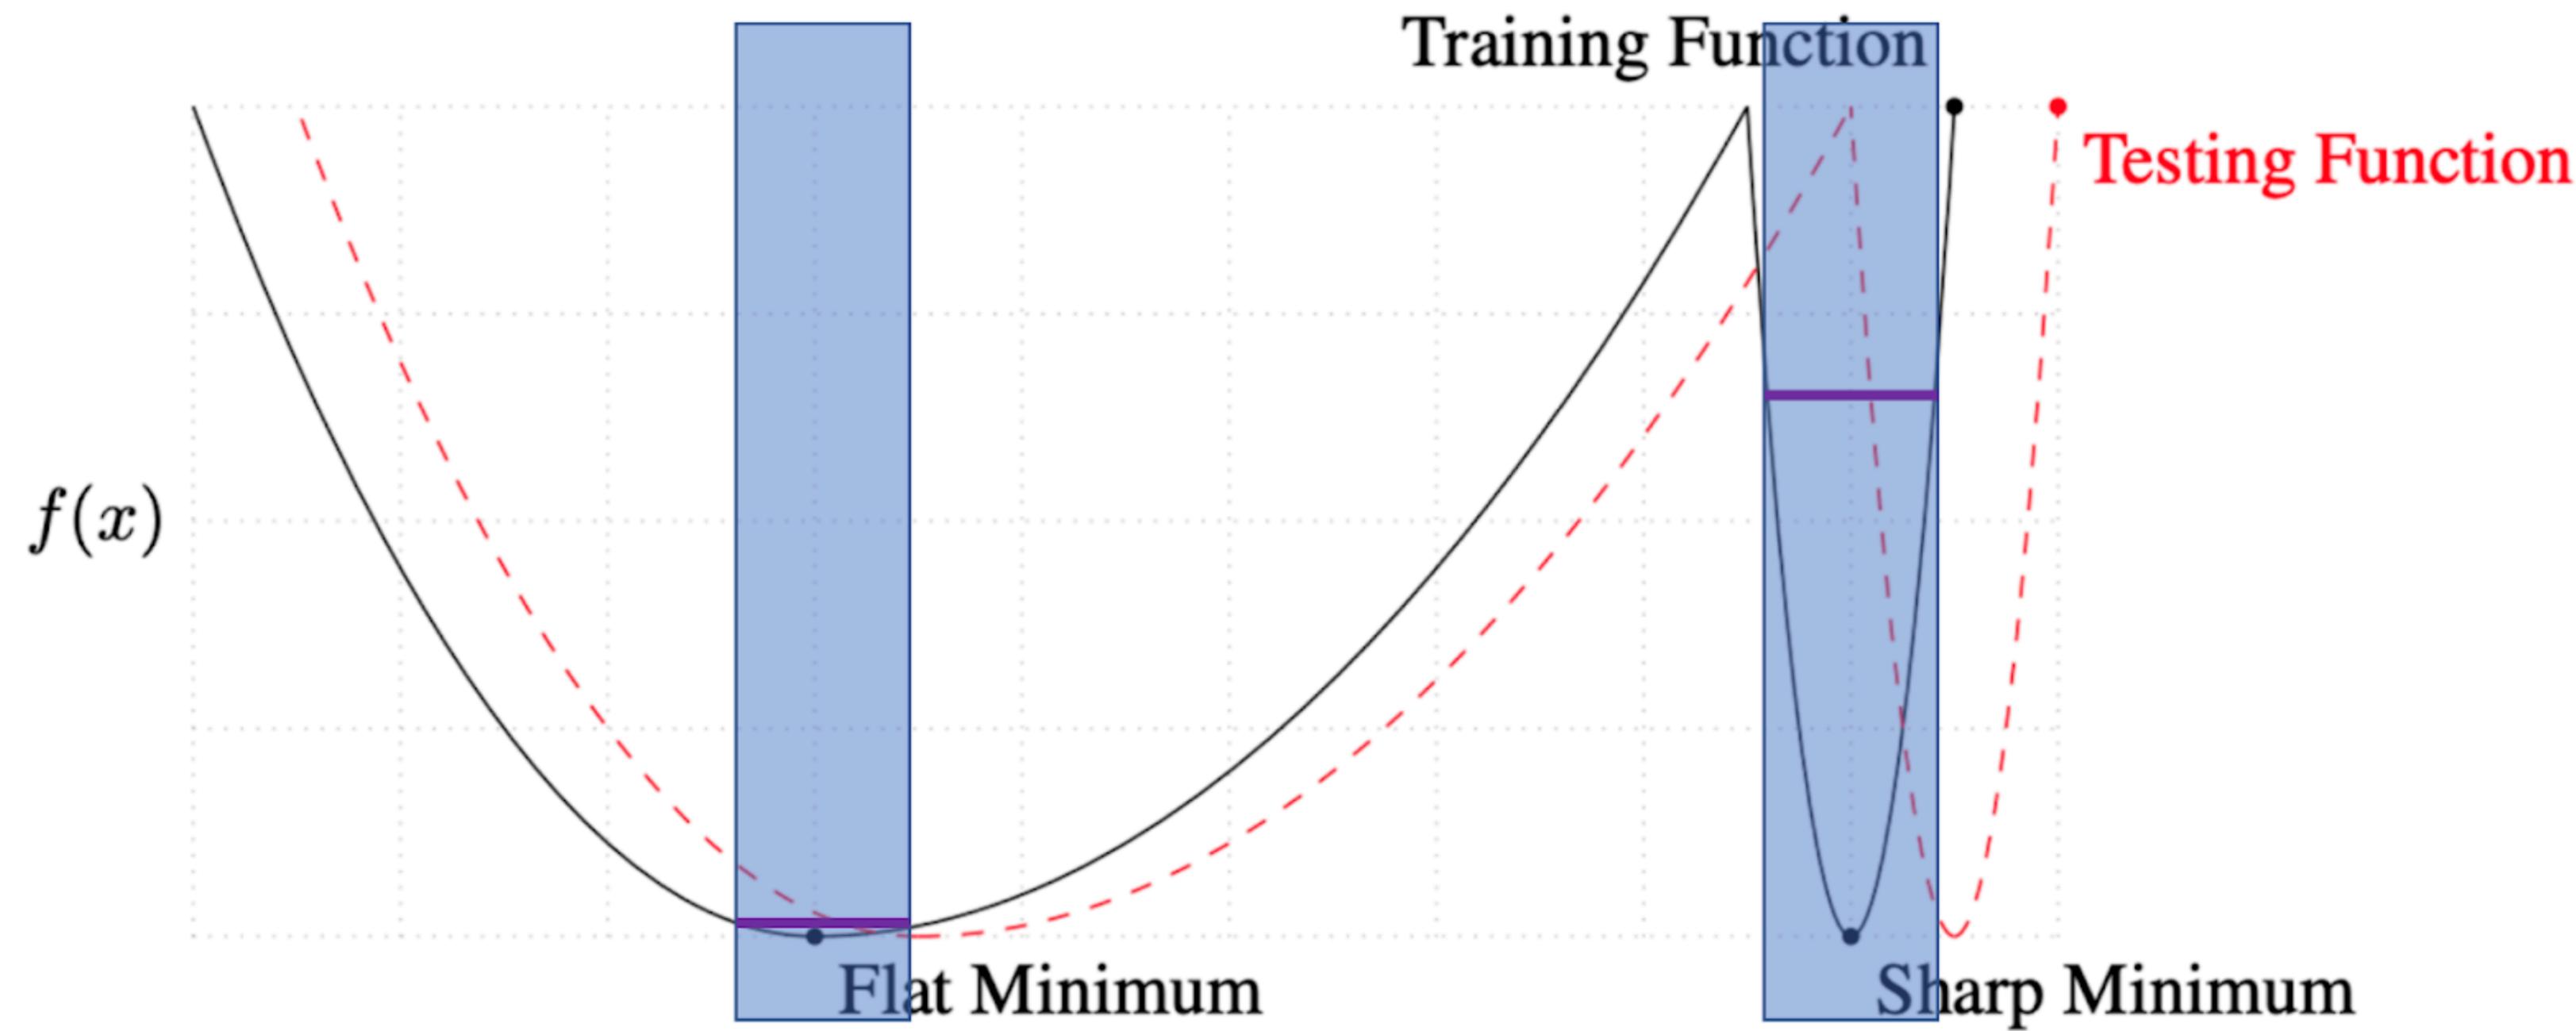

- Conduct the following update for each iteration:

- $w \leftarrow w - \alpha \nabla L(w + \hat{\delta})$

# Vision Transformer (ViT)

## Sharpness Aware Minimization (SAM)

- SAM is a natural way to penalize sharpness region (but requires some computational overhead)

# **Unsupervised learning for NLP**

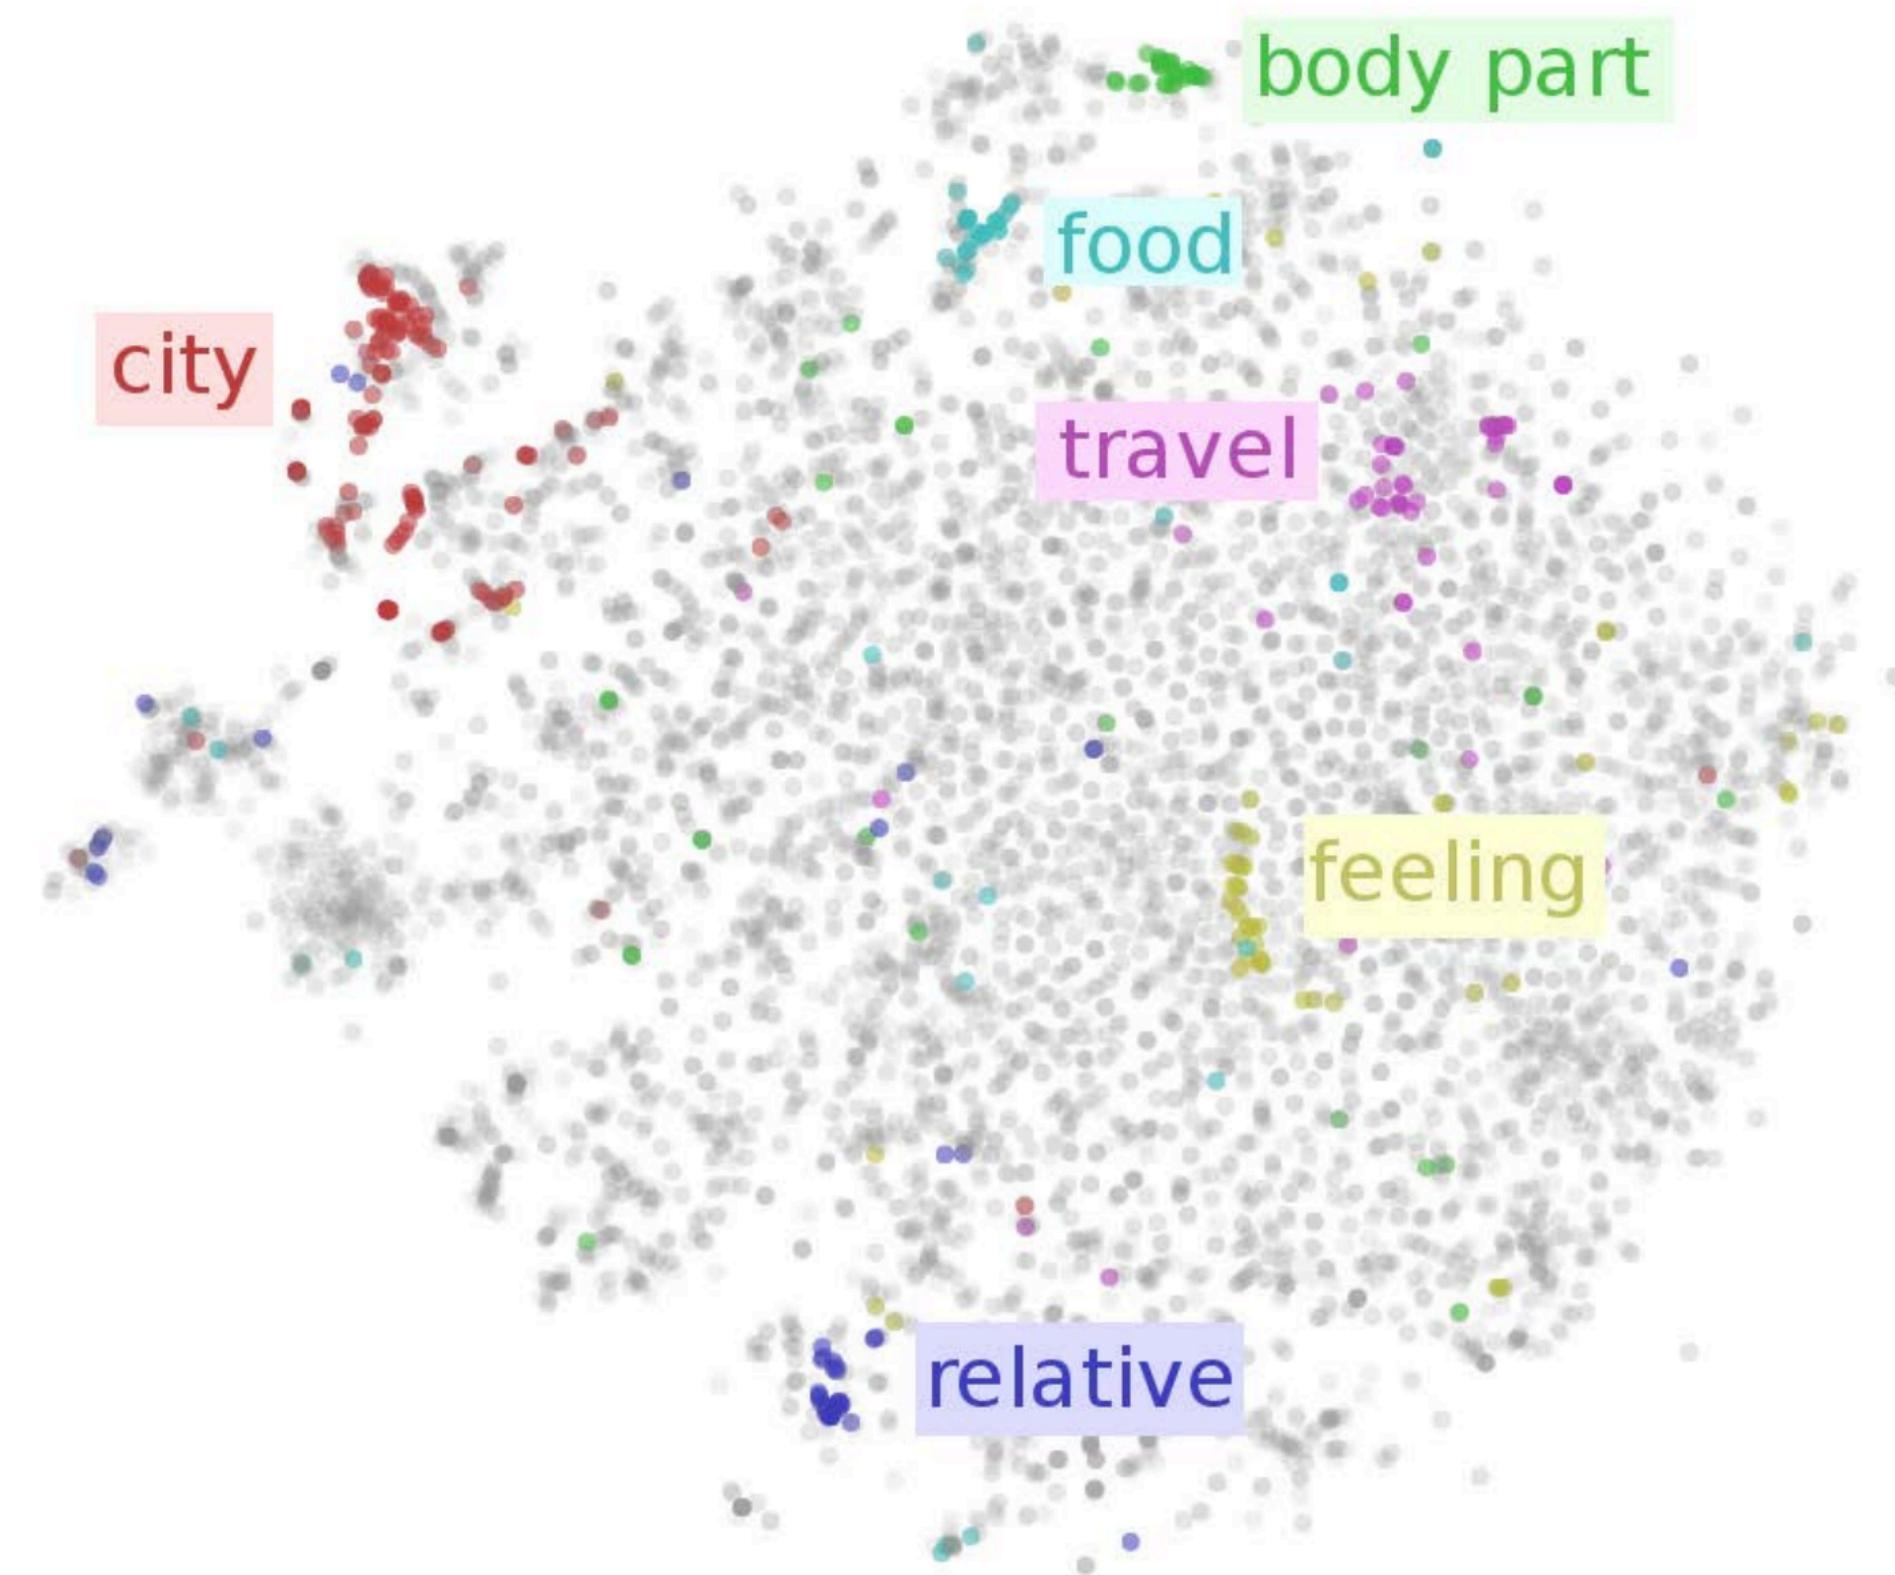

## **Motivation**

- Many unlabeled NLP data but very few labeled data
- Can we use large amount of unlabeled data to obtain meaningful representations of words/sentences?

# Unsupervised learning for NLP

## Learning word embeddings

- Use large (unlabeled) corpus to learn a useful word representation
  - Learn a vector for each word based on the corpus
  - Hopefully the vector represents some semantic meaning
  - Can be used for many tasks
    - Replace the word embedding matrix for DNN models for classification/translation
    - Two different perspectives but led to similar results:
      - Glove (Pennington et al., 2014)
      - Word2vec (Mikolov et al., 2013)

# Unsupervised learning for NLP

## Context information

- Given a large text corpus, how to learn **low-dimensional features** to represent a word?
- For each word  $w_i$ , define the “**contexts**” of the word as the words surrounding it in an  $L$ -sized window:
  - $w_{i-L-2}, w_{i-L-1}, \underbrace{w_{i-L}, \dots, w_{i-1}}_{\text{contexts of } w_i}, \underbrace{w_i}_{\text{word}}, \underbrace{w_{i+1}, \dots, w_{i+L}}_{\text{contexts of } w_i}, w_{i+L+1}, \dots$
- Get a collection of (word, context) pairs, denoted by  $D$ .

# Unsupervised pertaining for NLP

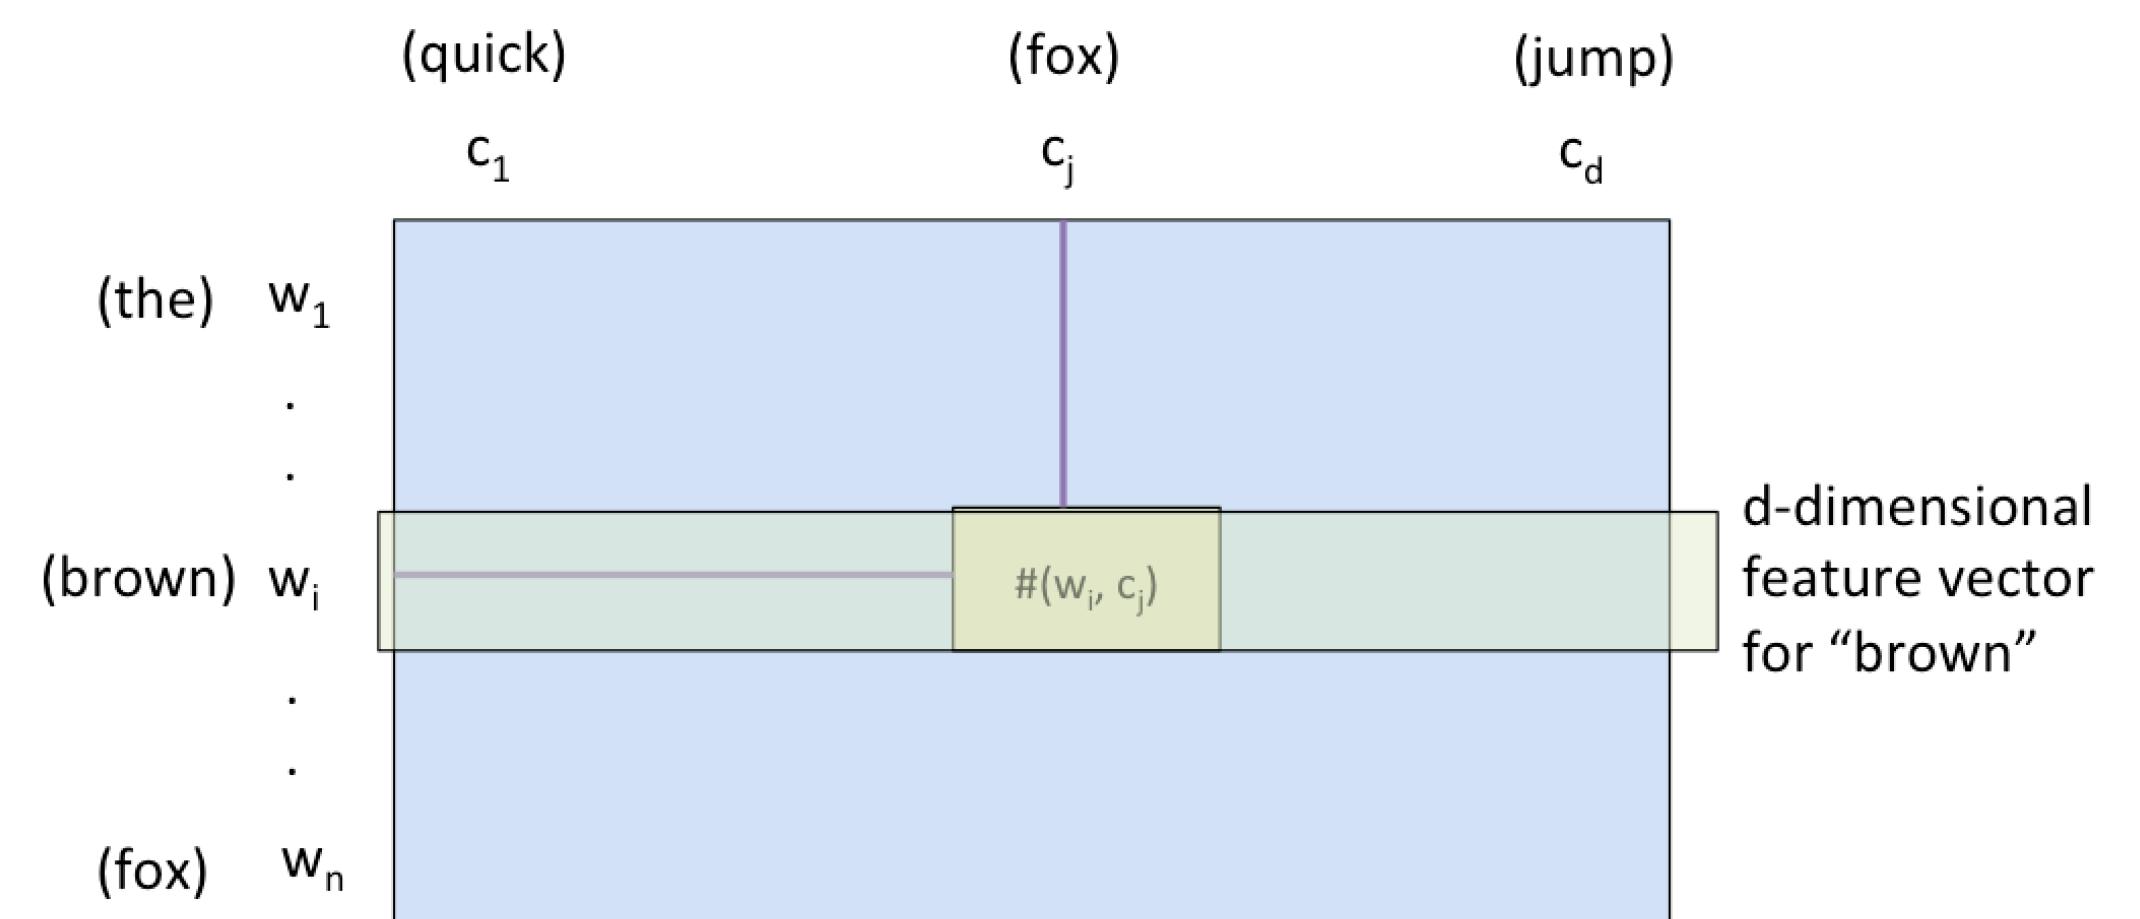

## Examples

Source Text	Training Samples
The <b>quick</b> brown fox jumps over the lazy dog. →	(the, quick) (the, brown)
The quick <b>brown</b> fox jumps over the lazy dog. →	(quick, the) (quick, brown) (quick, fox)
The quick brown <b>fox</b> jumps over the lazy dog. →	(brown, the) (brown, quick) (brown, fox) (brown, jumps)
The quick brown fox <b>jumps</b> over the lazy dog. →	(fox, quick) (fox, brown) (fox, jumps) (fox, over)

# Unsupervised pertaining for NLP

## Use bag-of-word model

- Idea 1: Use the bag-of-word model to ``describe'' each word
- Assume we have context words  $c_1, \dots, c_d$  in the corpus, compute
  - $\#(w, c_i) :=$  number of times the pair  $(w, c_i)$  appears in  $D$
- For each word  $w$ , form a  $d$ -dimensional (sparse) vector to describe  $w$ 
  - $\#(w, c_1), \dots, \#(w, c_d)$ ,

# Unsupervised pertaining for NLP

## PMI/PPMI Representation

- Similar to TF-IDF: Need to consider the frequency of each word and each context
- Instead of using co-ocurrent count  $\#(w, c)$ , we can define pointwise mutual information:

$$\bullet \text{ PMI}(w, c) = \log\left(\frac{\hat{P}(w, c)}{\hat{P}(w)\hat{P}(c)}\right) = \log \frac{\#(w, c)|D|}{\#(w)\#(c)},$$

$$\bullet \#(w) = \sum_c \#(w, c): \text{number of times word } w \text{ occurred in } D$$

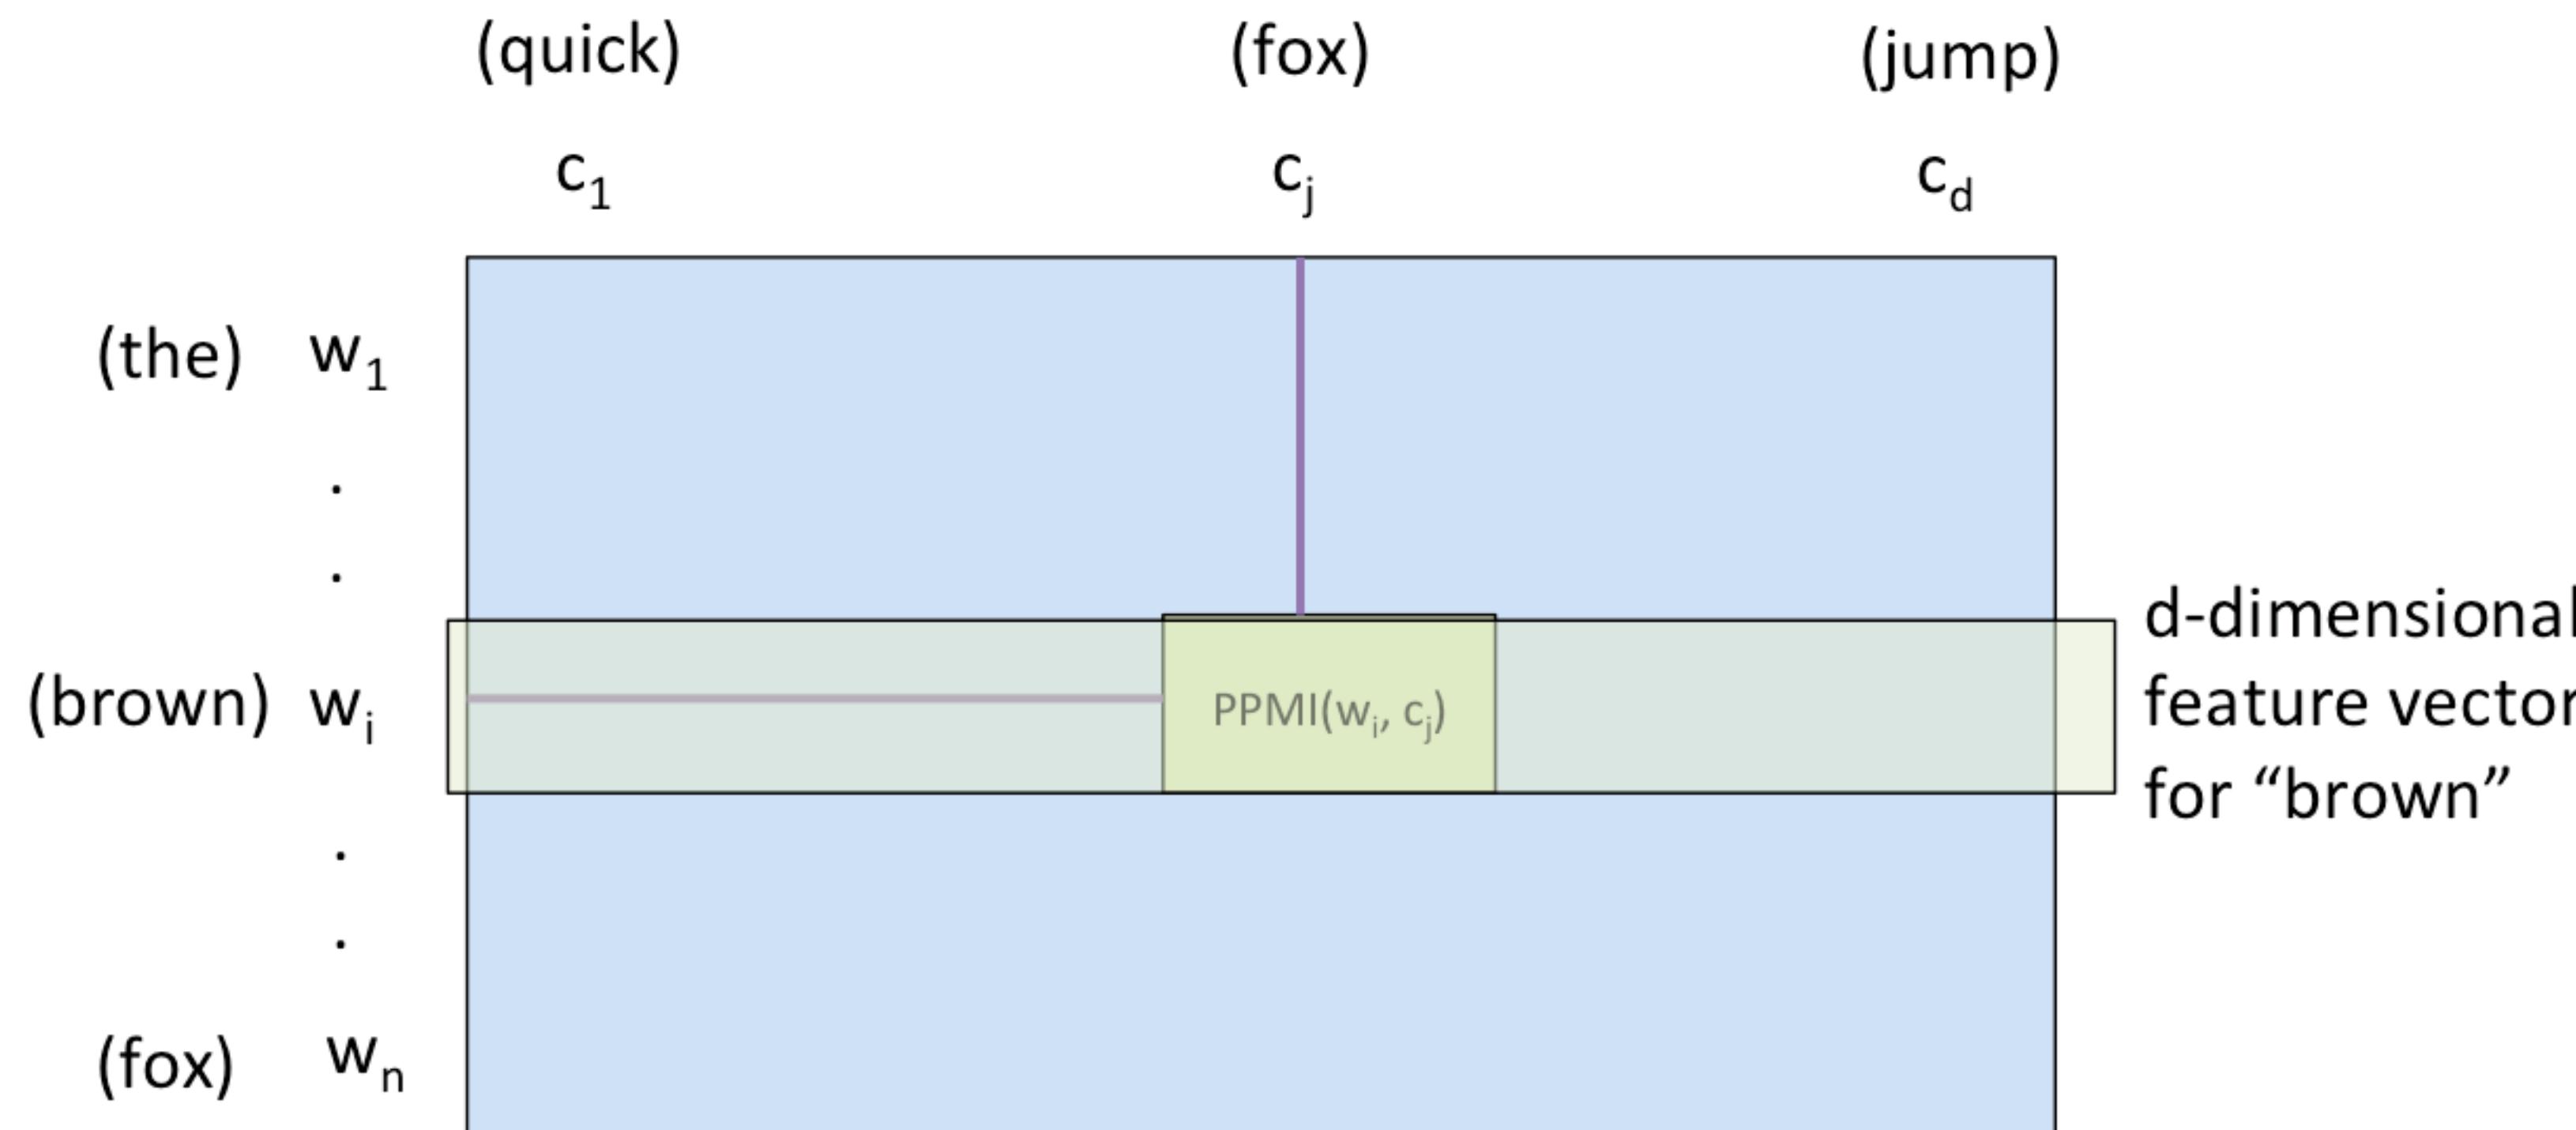

$$\bullet \#(c) = \sum_w \#(w, c): \text{number of times context } c \text{ occurred}$$

- $|D|$ : number of pairs in  $D$
- Positive PMI (PPMI) usually achieves better performance:

- $\text{PPMI}(w, c) = \max(\text{PMI}(w, c), 0)$
- $M^{\text{PPMI}}$ : a  $n$  by  $d$  word feature matrix, each row is a word and each column is a context

# Unsupervised pertaining for NLP

## PPMI Matrix

# Unsupervised pertaining for NLP

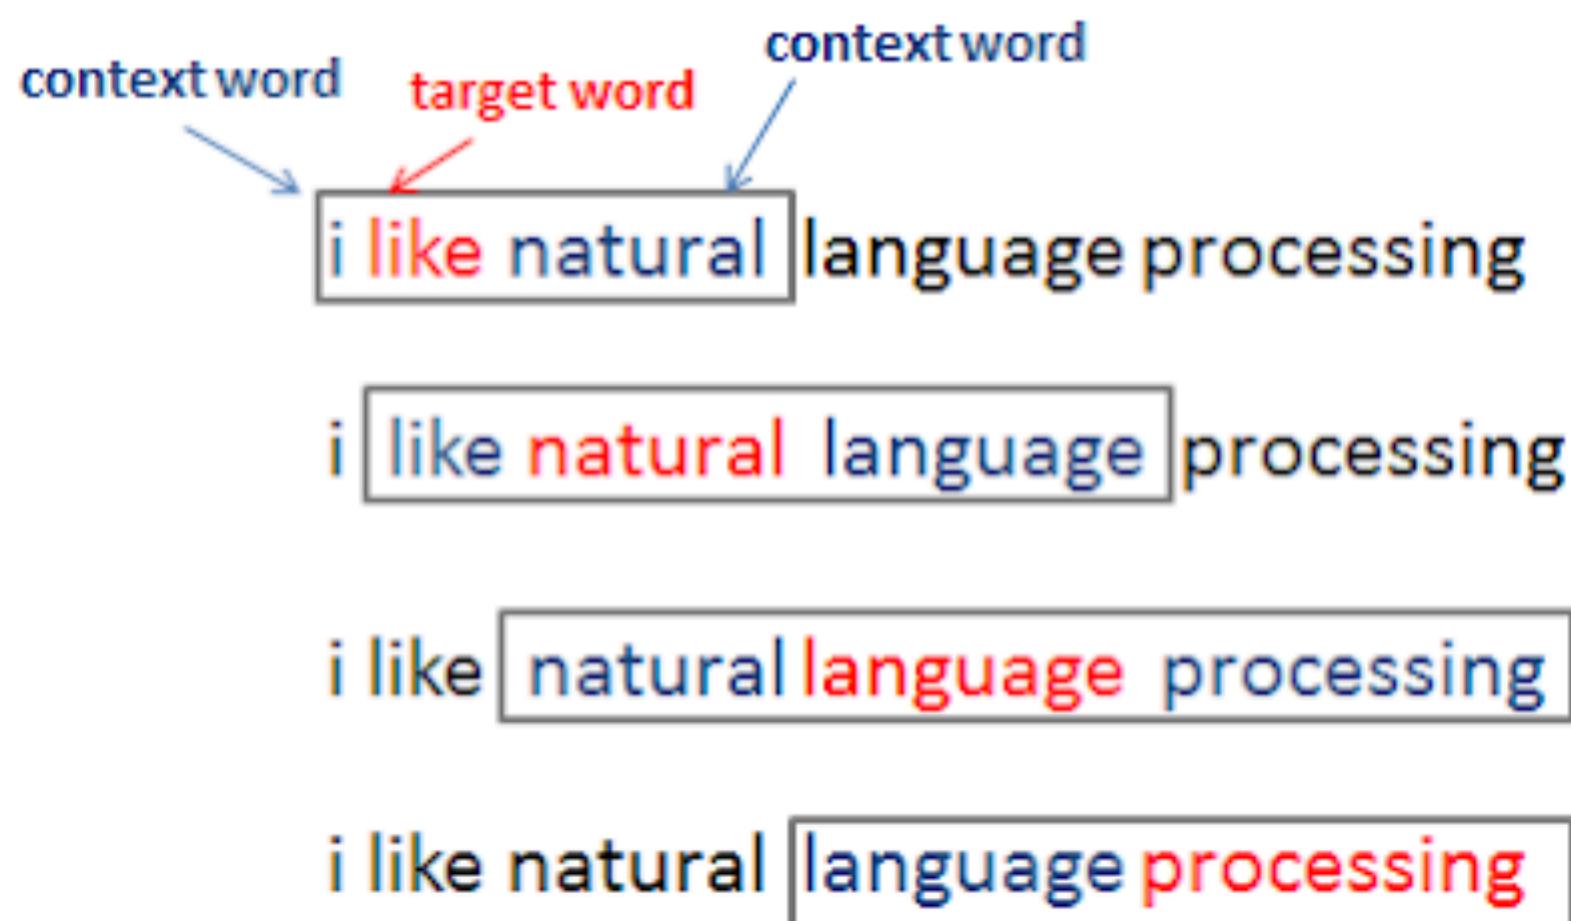

## Generalized Low-rank Embedding

- SVD basis will minimize
  - $\min_{W,V} \|M^{\text{PPMI}} - WV^T\|_F^2$
- Glove (Pennington et al., 2014)
  - Negative sampling (less weights to 0s in  $M^{\text{PPMI}}$ )
  - Adding bias term:
    - $M^{\text{PPMI}} \approx WV^T + b_w e^T + e b_c^T$
- Use  $W$  or  $V$  as the word embedding matrix

# Unsupervised learning for NLP

## Word2vec (Mikolov et al., 2013)

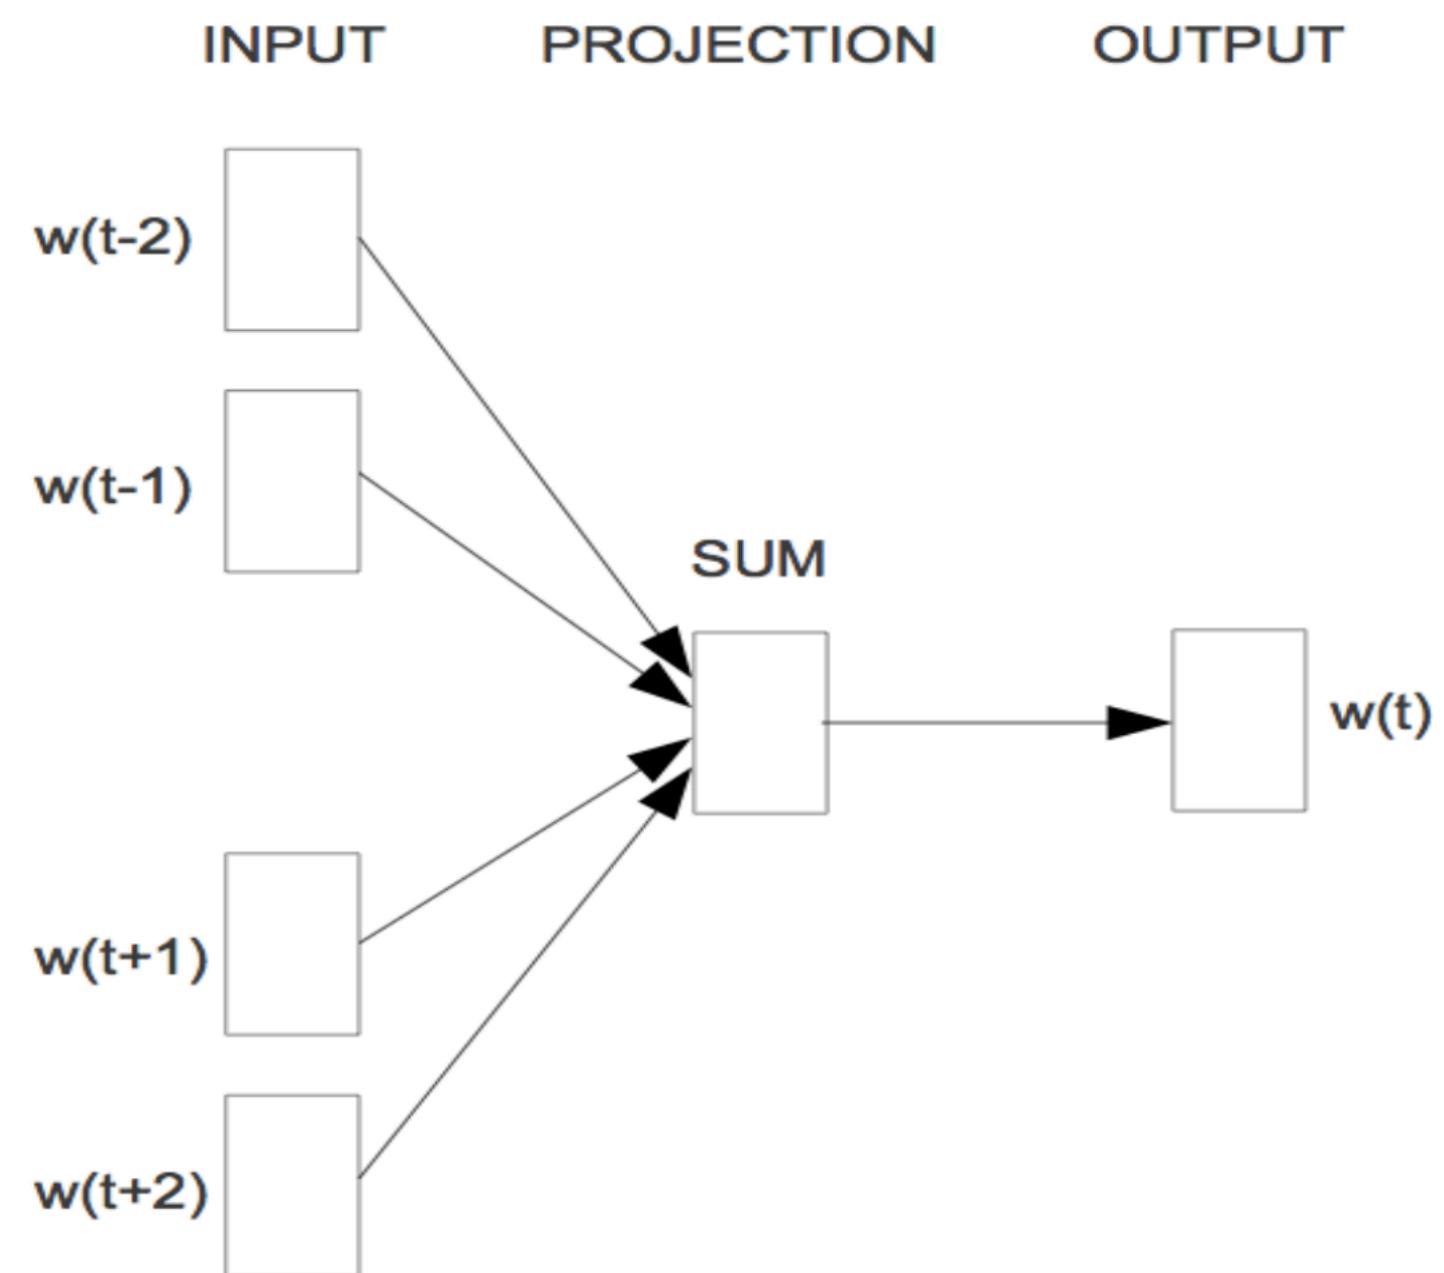

- A neural network model for learning word embeddings
- Main idea:
  - Predict the target words based on the neighbors (CBOW)
  - Predict neighbors given the target words (Skip-gram)

# Unsupervised learning for NLP

## CBOW (Continuous Bag-of-Words model)

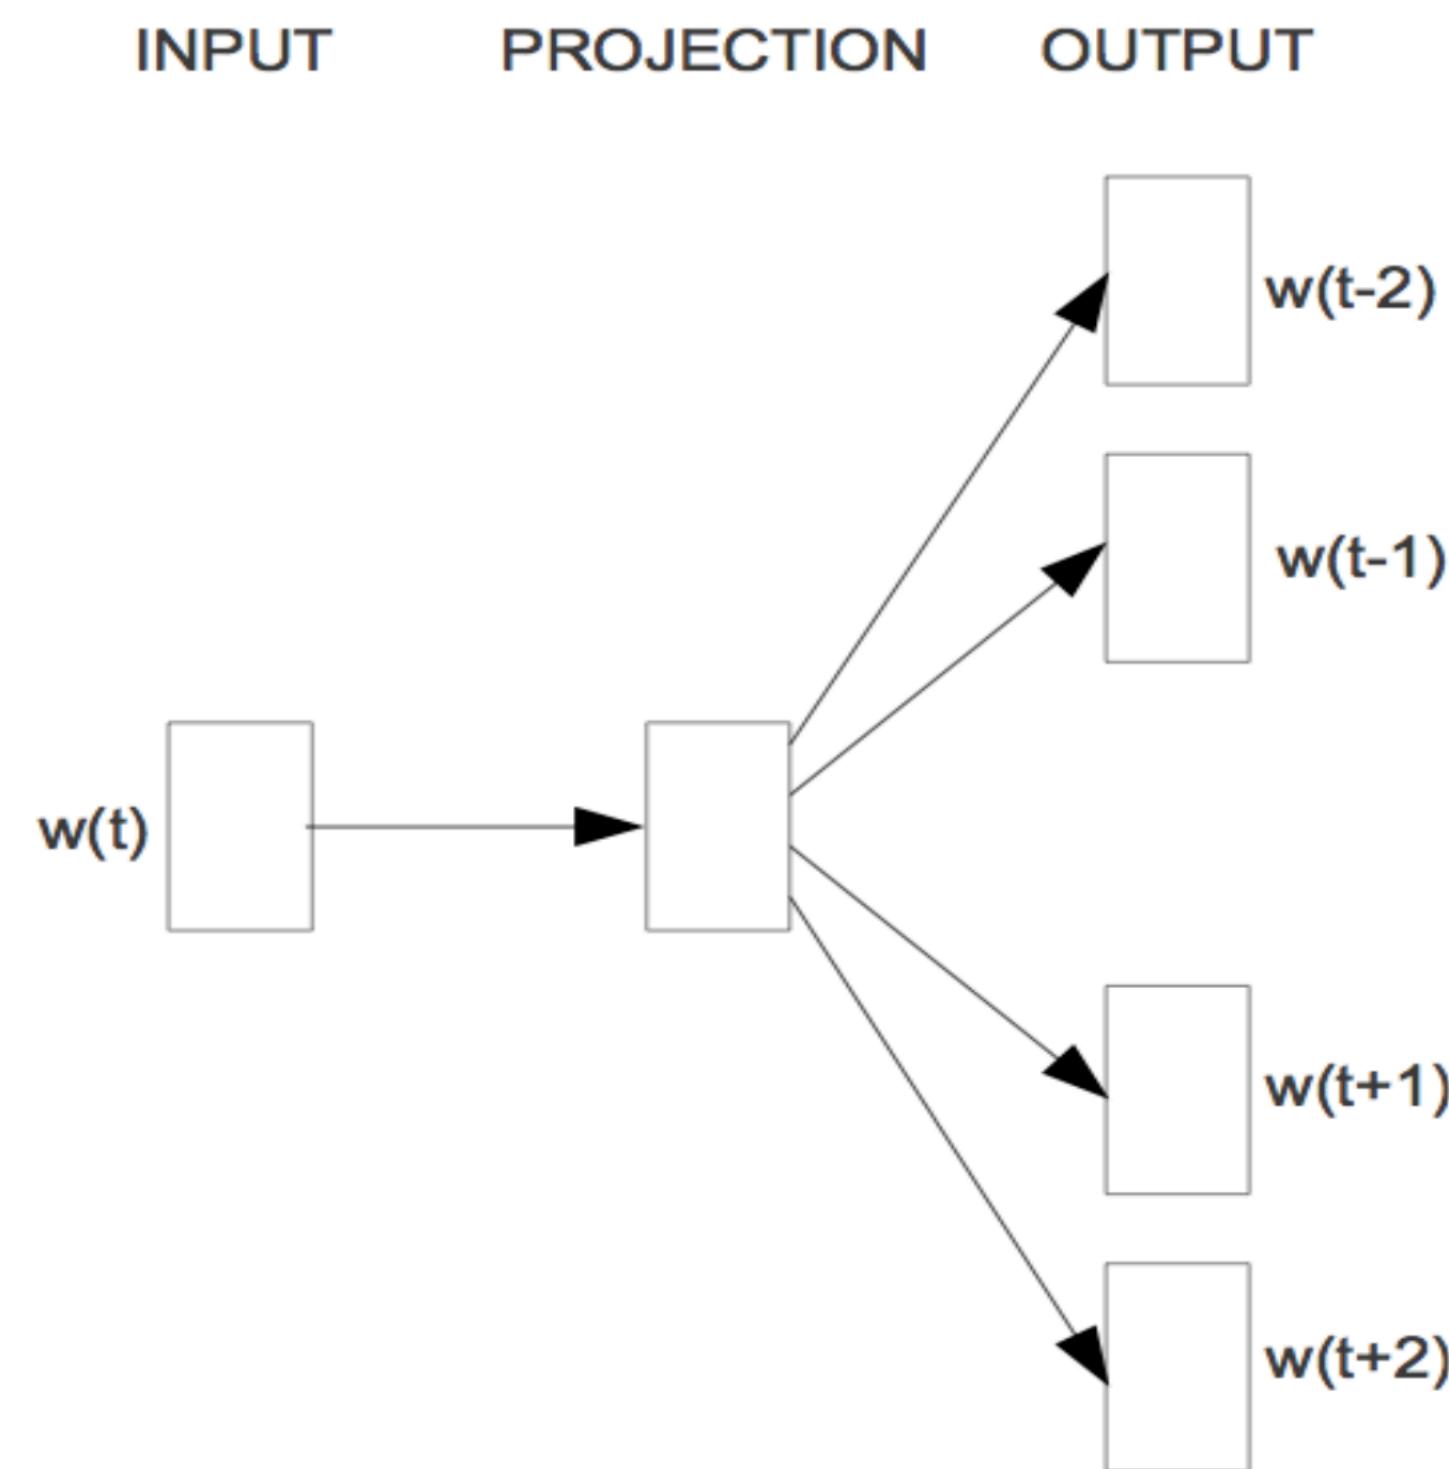

- Predict the target words based on the neighbors

# Unsupervised pertaining for NLP

## Skip-gram

- Predict neighbors using target word

# Unsupervised pertaining for NLP

## More on skip-gram

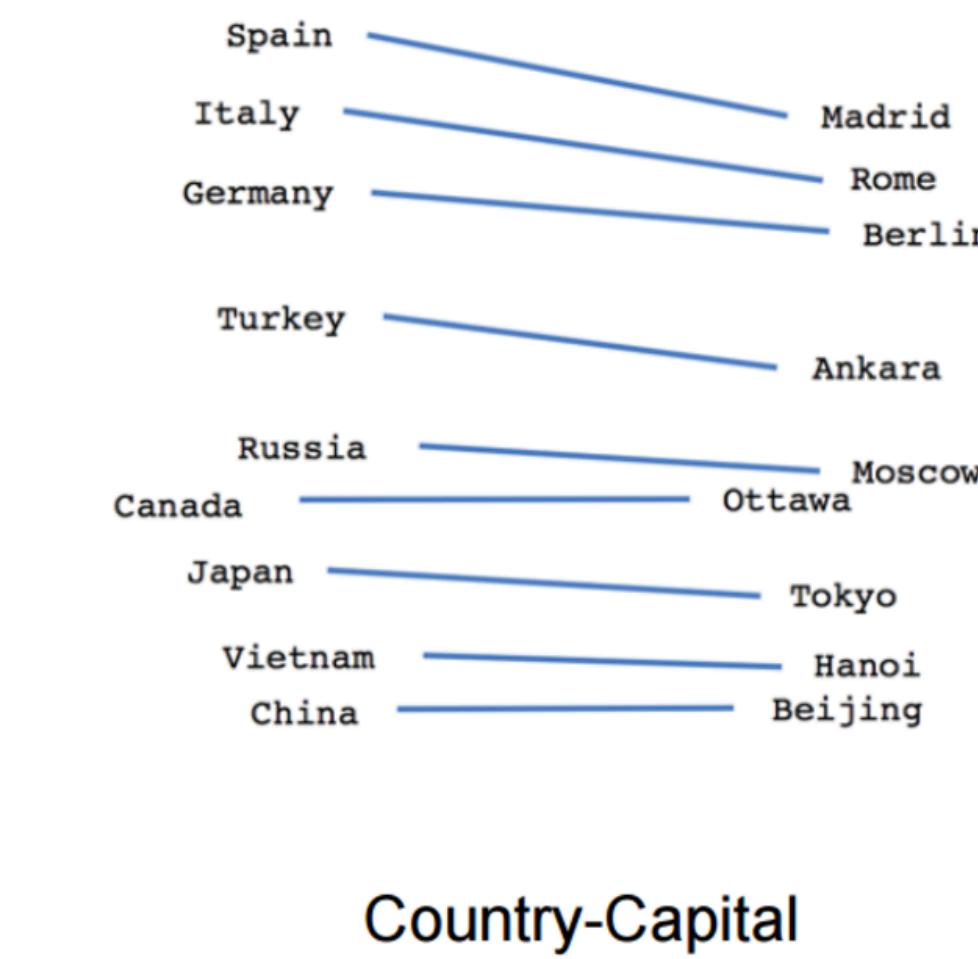

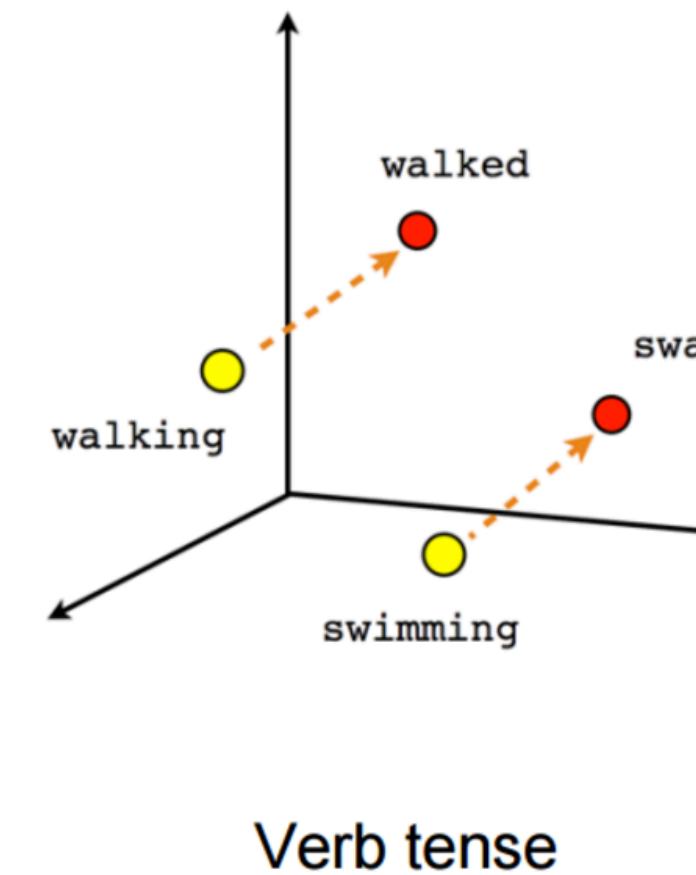

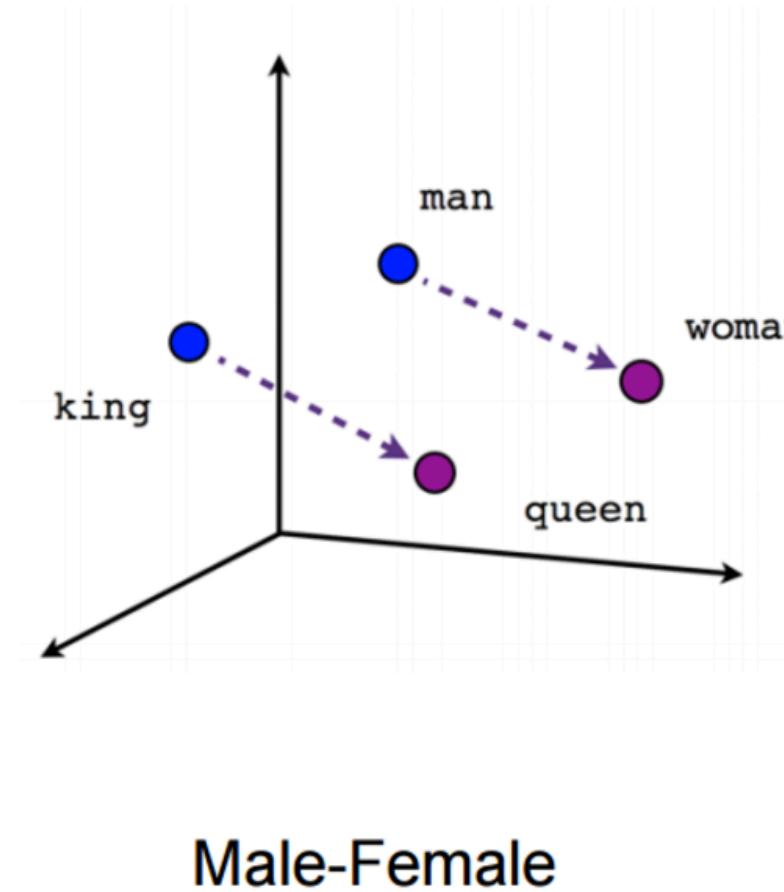

- Learn the probability  $P(w_{t+j} | w_t)$ : the probability to see  $w_{t+j}$  in target word  $w_t$ 's neighborhood
- Every word has two embeddings:
  - $v_i$  serves as the role of target
  - $u_i$  serves as the role of context
- Model probability as softmax:

$$\bullet \quad P(o | c) = \frac{e^{u_o^T v_c}}{\sum_{w=1}^W e^{u_w^T v_c}}$$

# Unsupervised pertaining for NLP

## Results

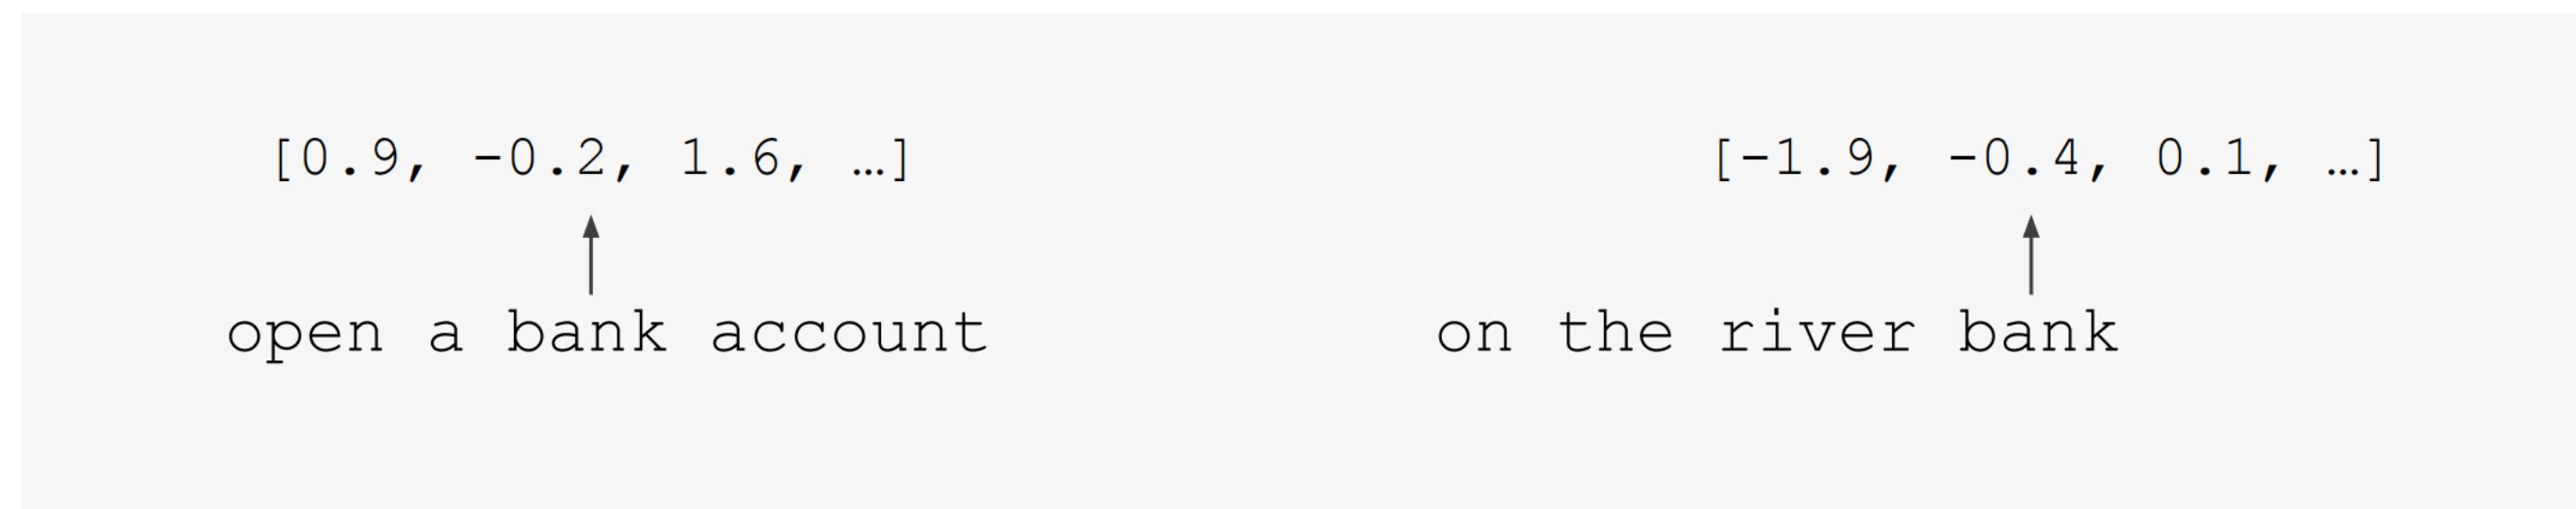

- The low-dimensional embeddings are (often) meaningful:

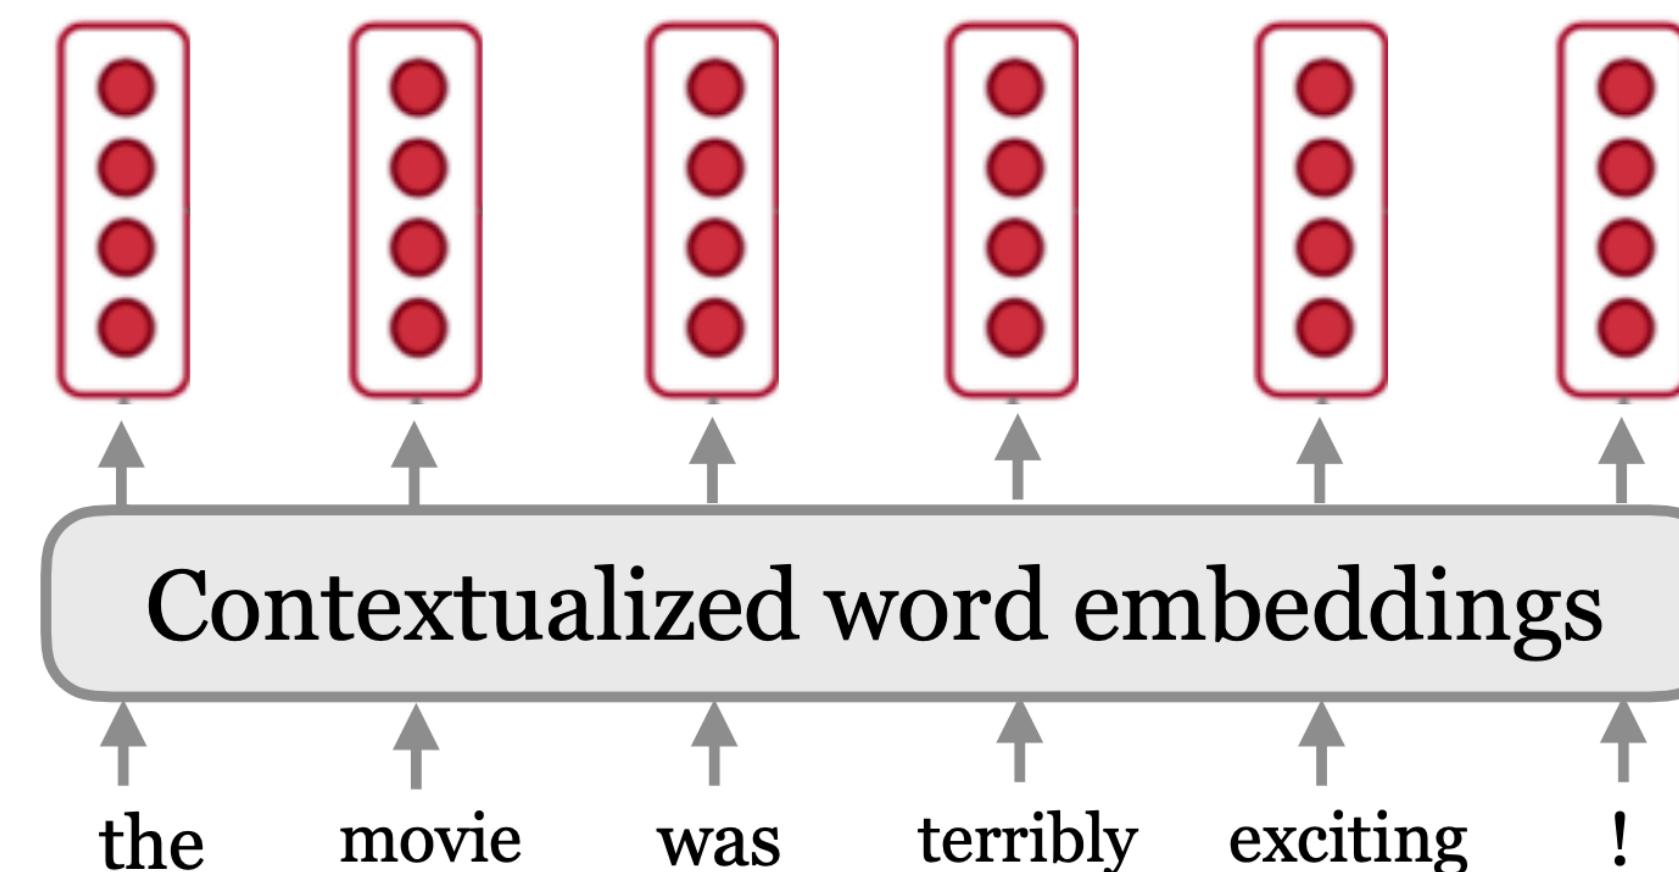

# Contextual embedding

## Contextual word representation

- The semantic meaning of a word should depend on its context

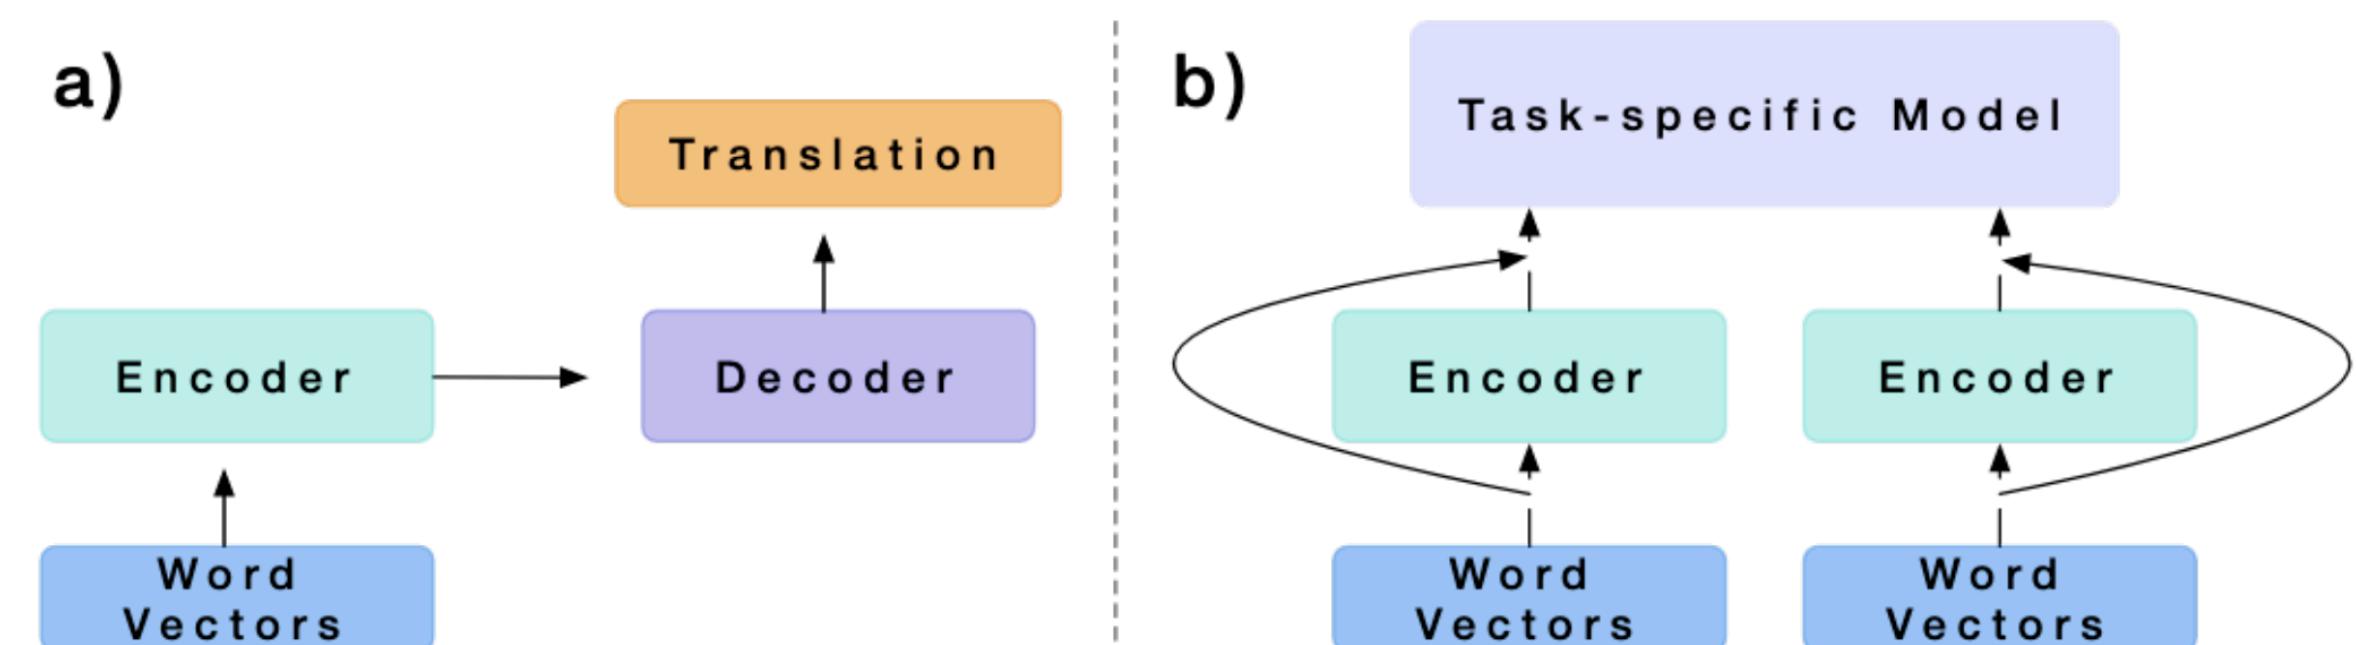

- Solution: Train a model to extract contextual representations on text corpus

# Contextual embedding

CoVe (McCann et al., 2017)

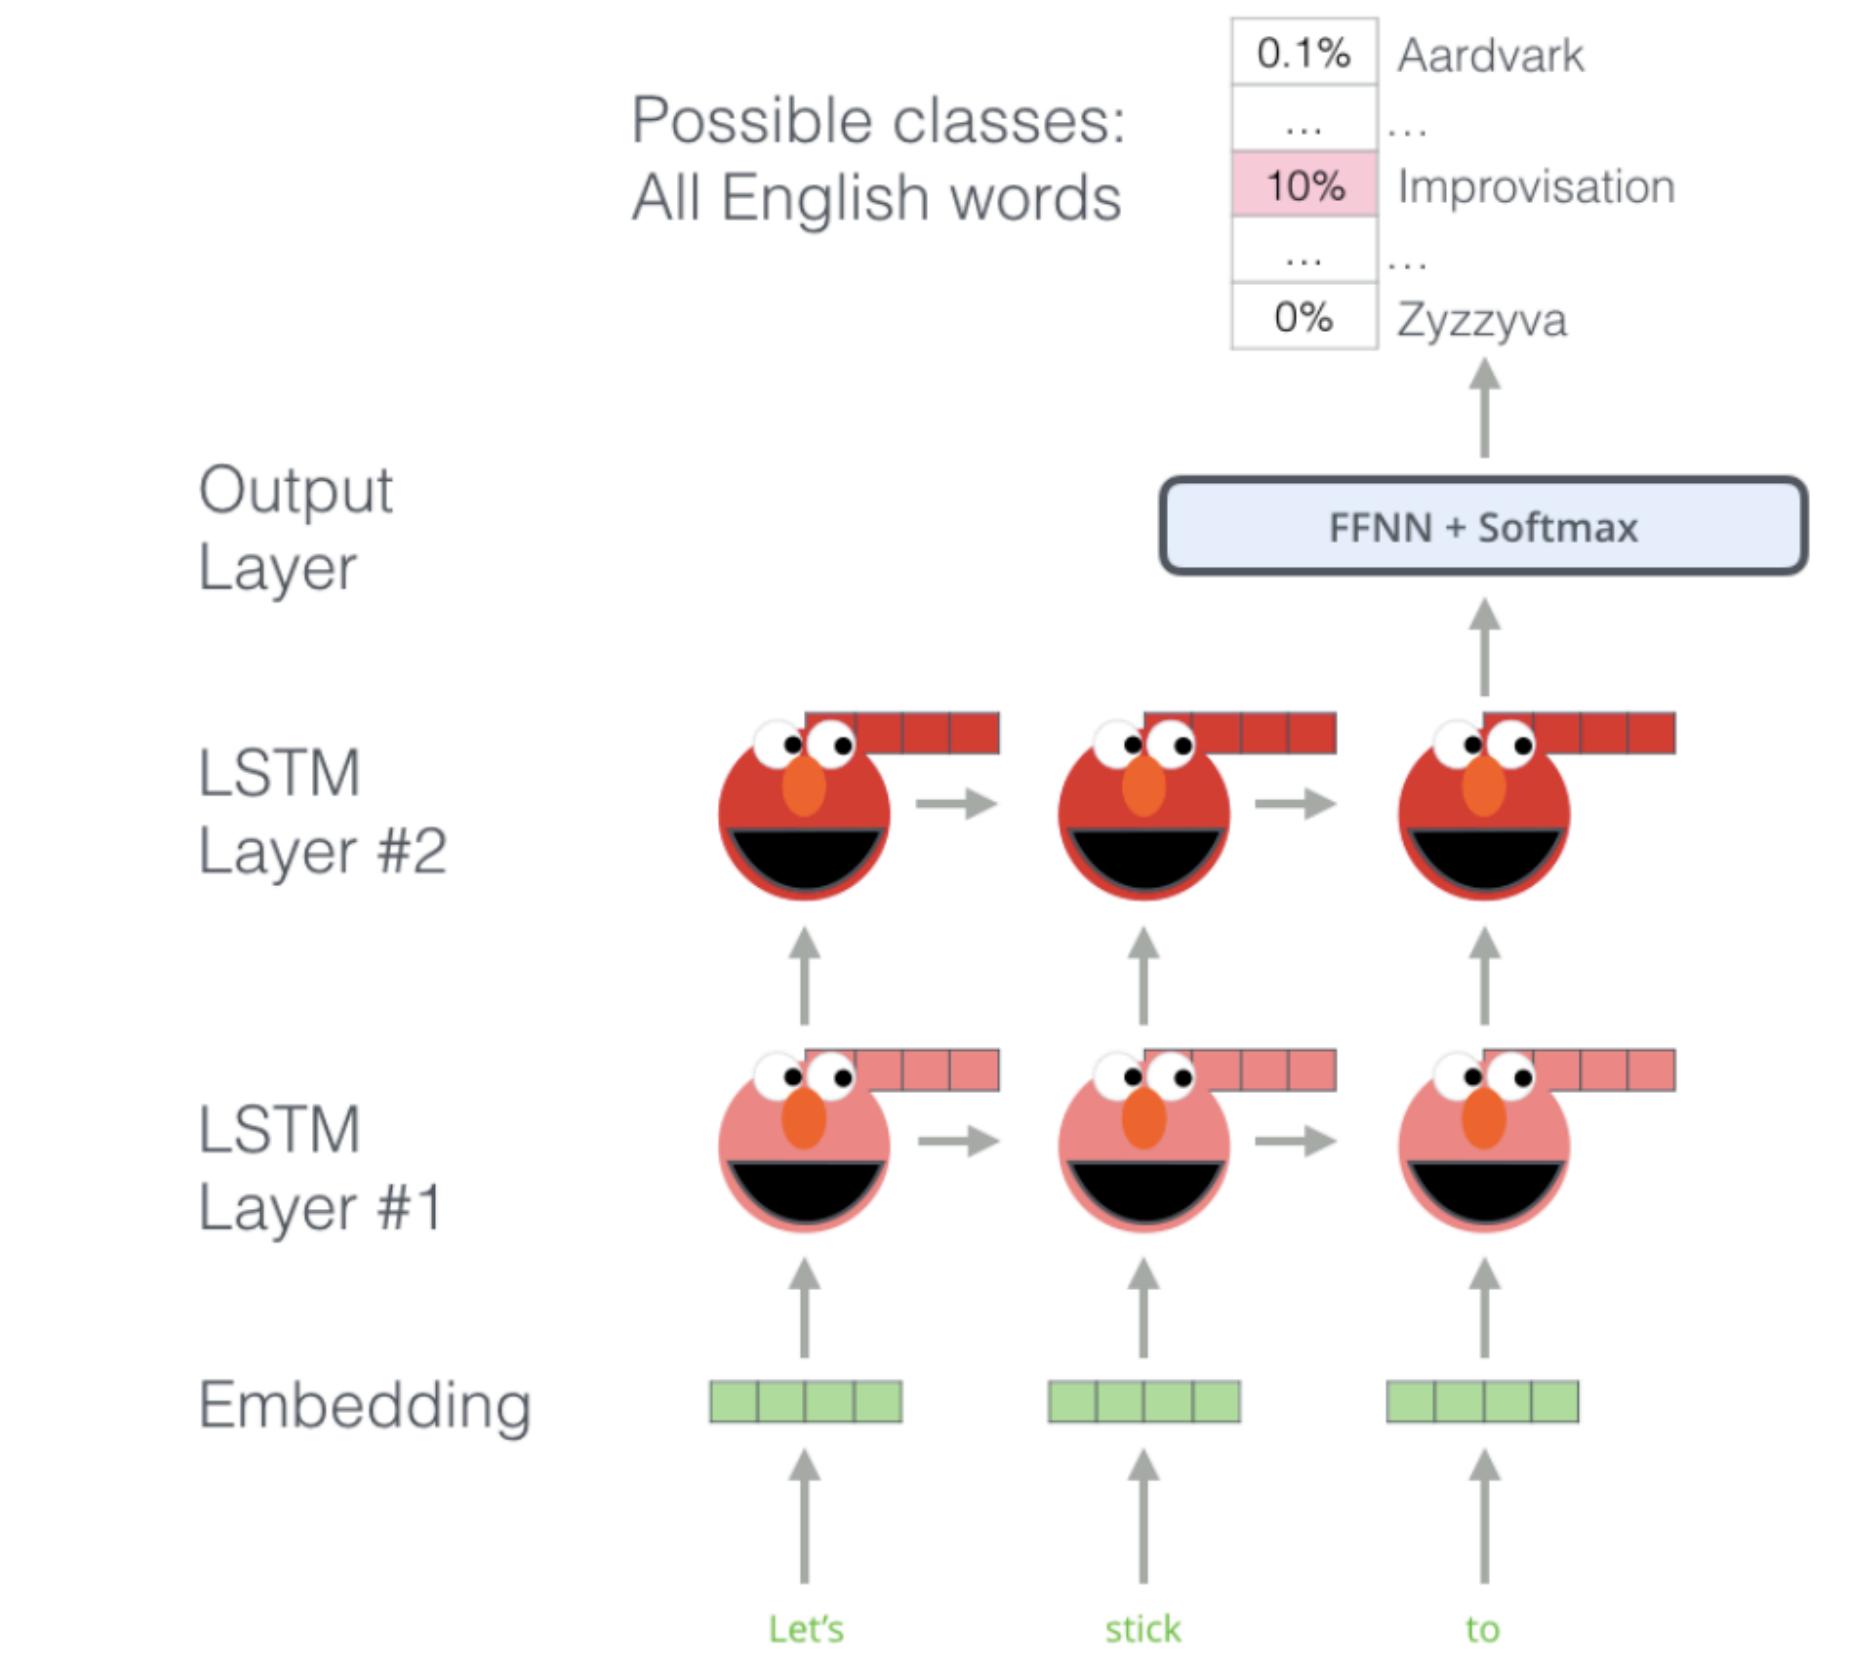

- Key idea: Train a standard neural machine translation model
- Take the encoder directly as contextualized word embeddings
- Problems:
  - Translation requires paired (labeled) data
  - The embeddings are tailored to particular translation corpuses

# Contextual embedding

## Language model pretraining task

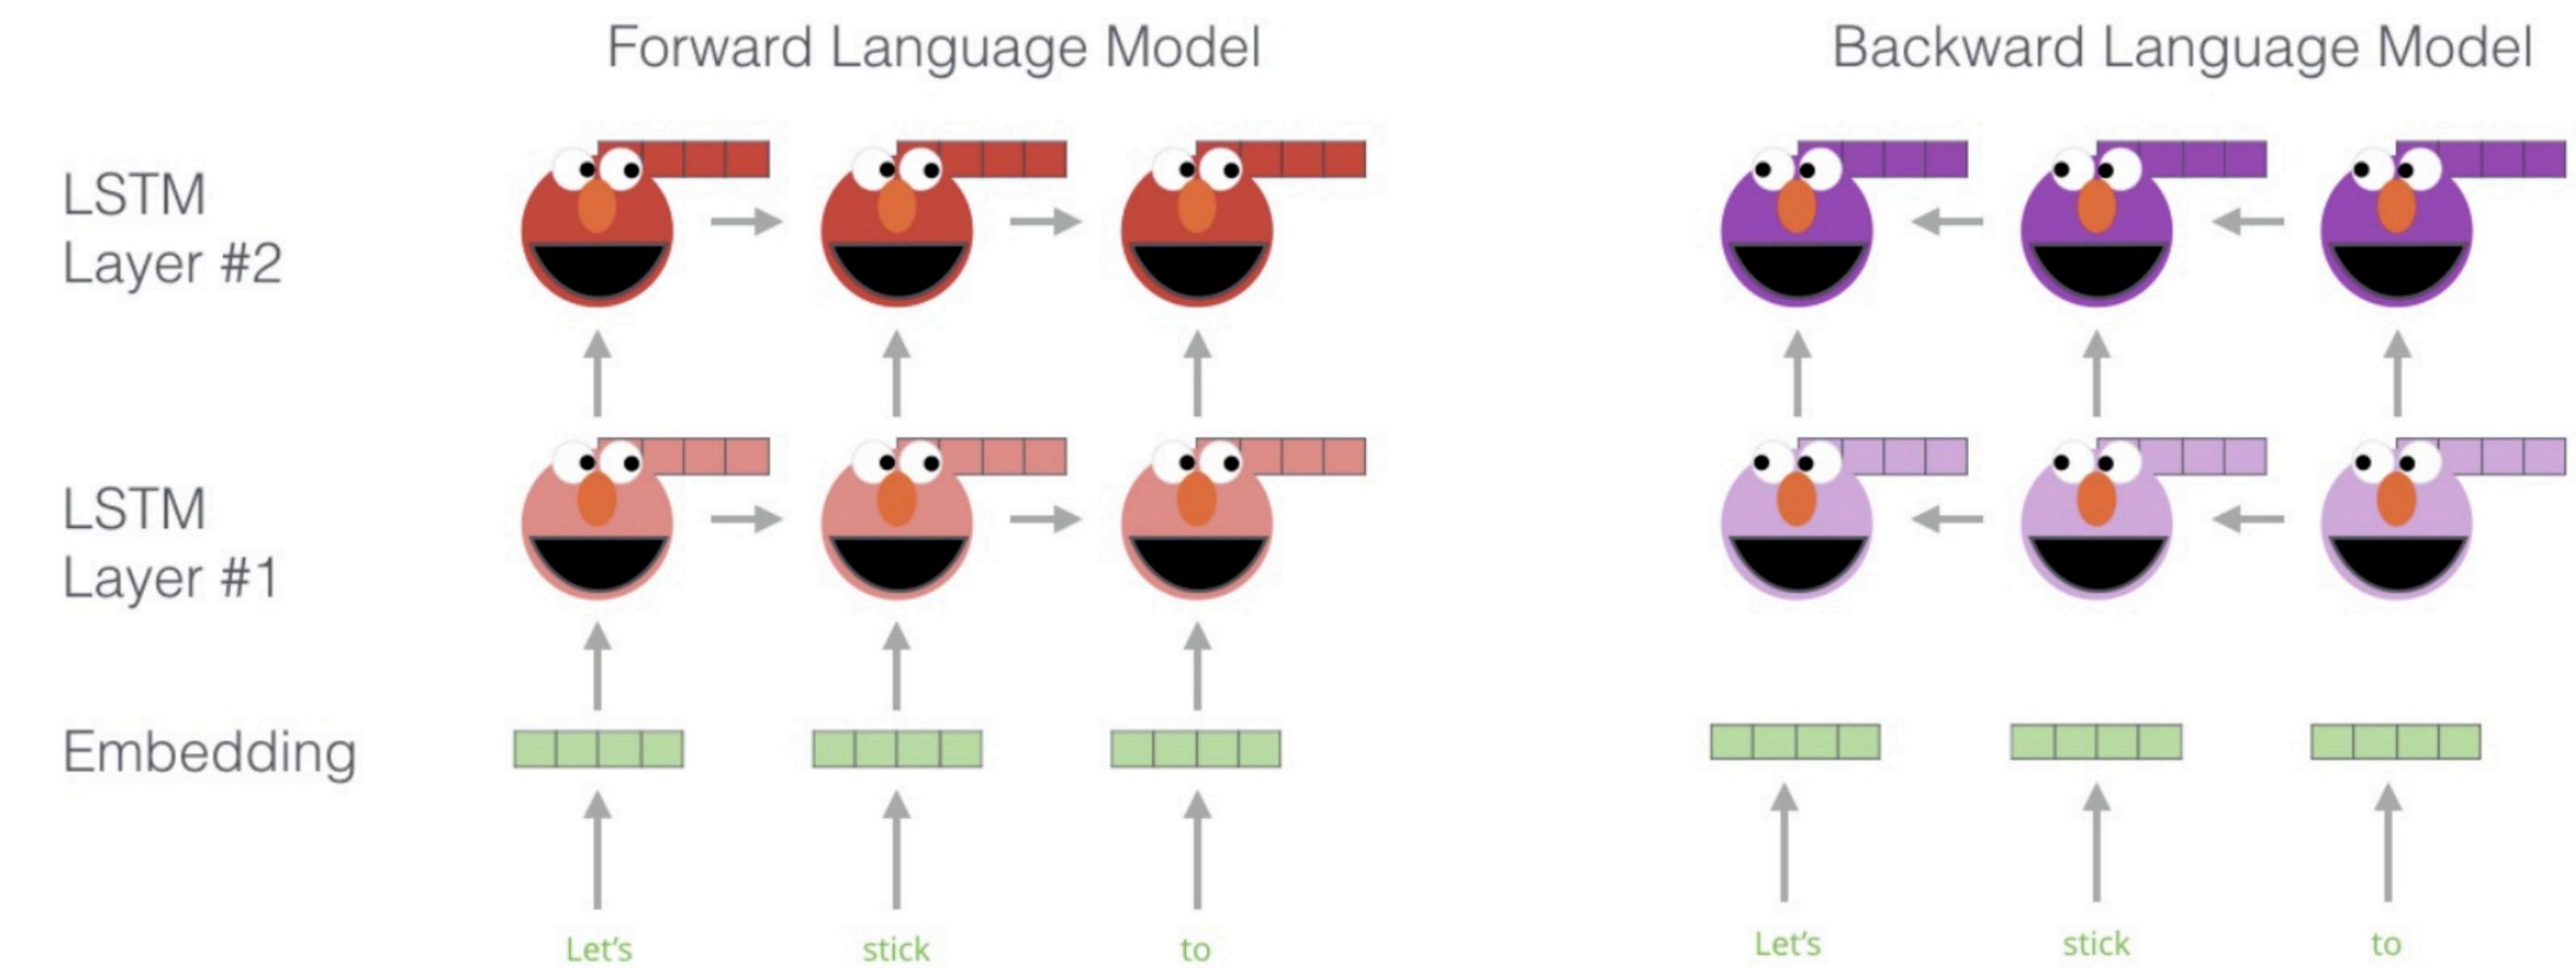

- Predict the next word given the prefix
- Can be defined on any unlabeled document

# Contextual embedding

## ELMo (Peter et al., 2018)

- Key ideas:
  - Train a forward and backward LSTM language model on large corpus
  - Use the hidden states for each token to compute a vector representation of each word
  - Replace the word embedding by Elmo's embedding (with fixed Elmo's LSTM weights)

# Contextual embedding

## ELMo results

# Contextual embedding

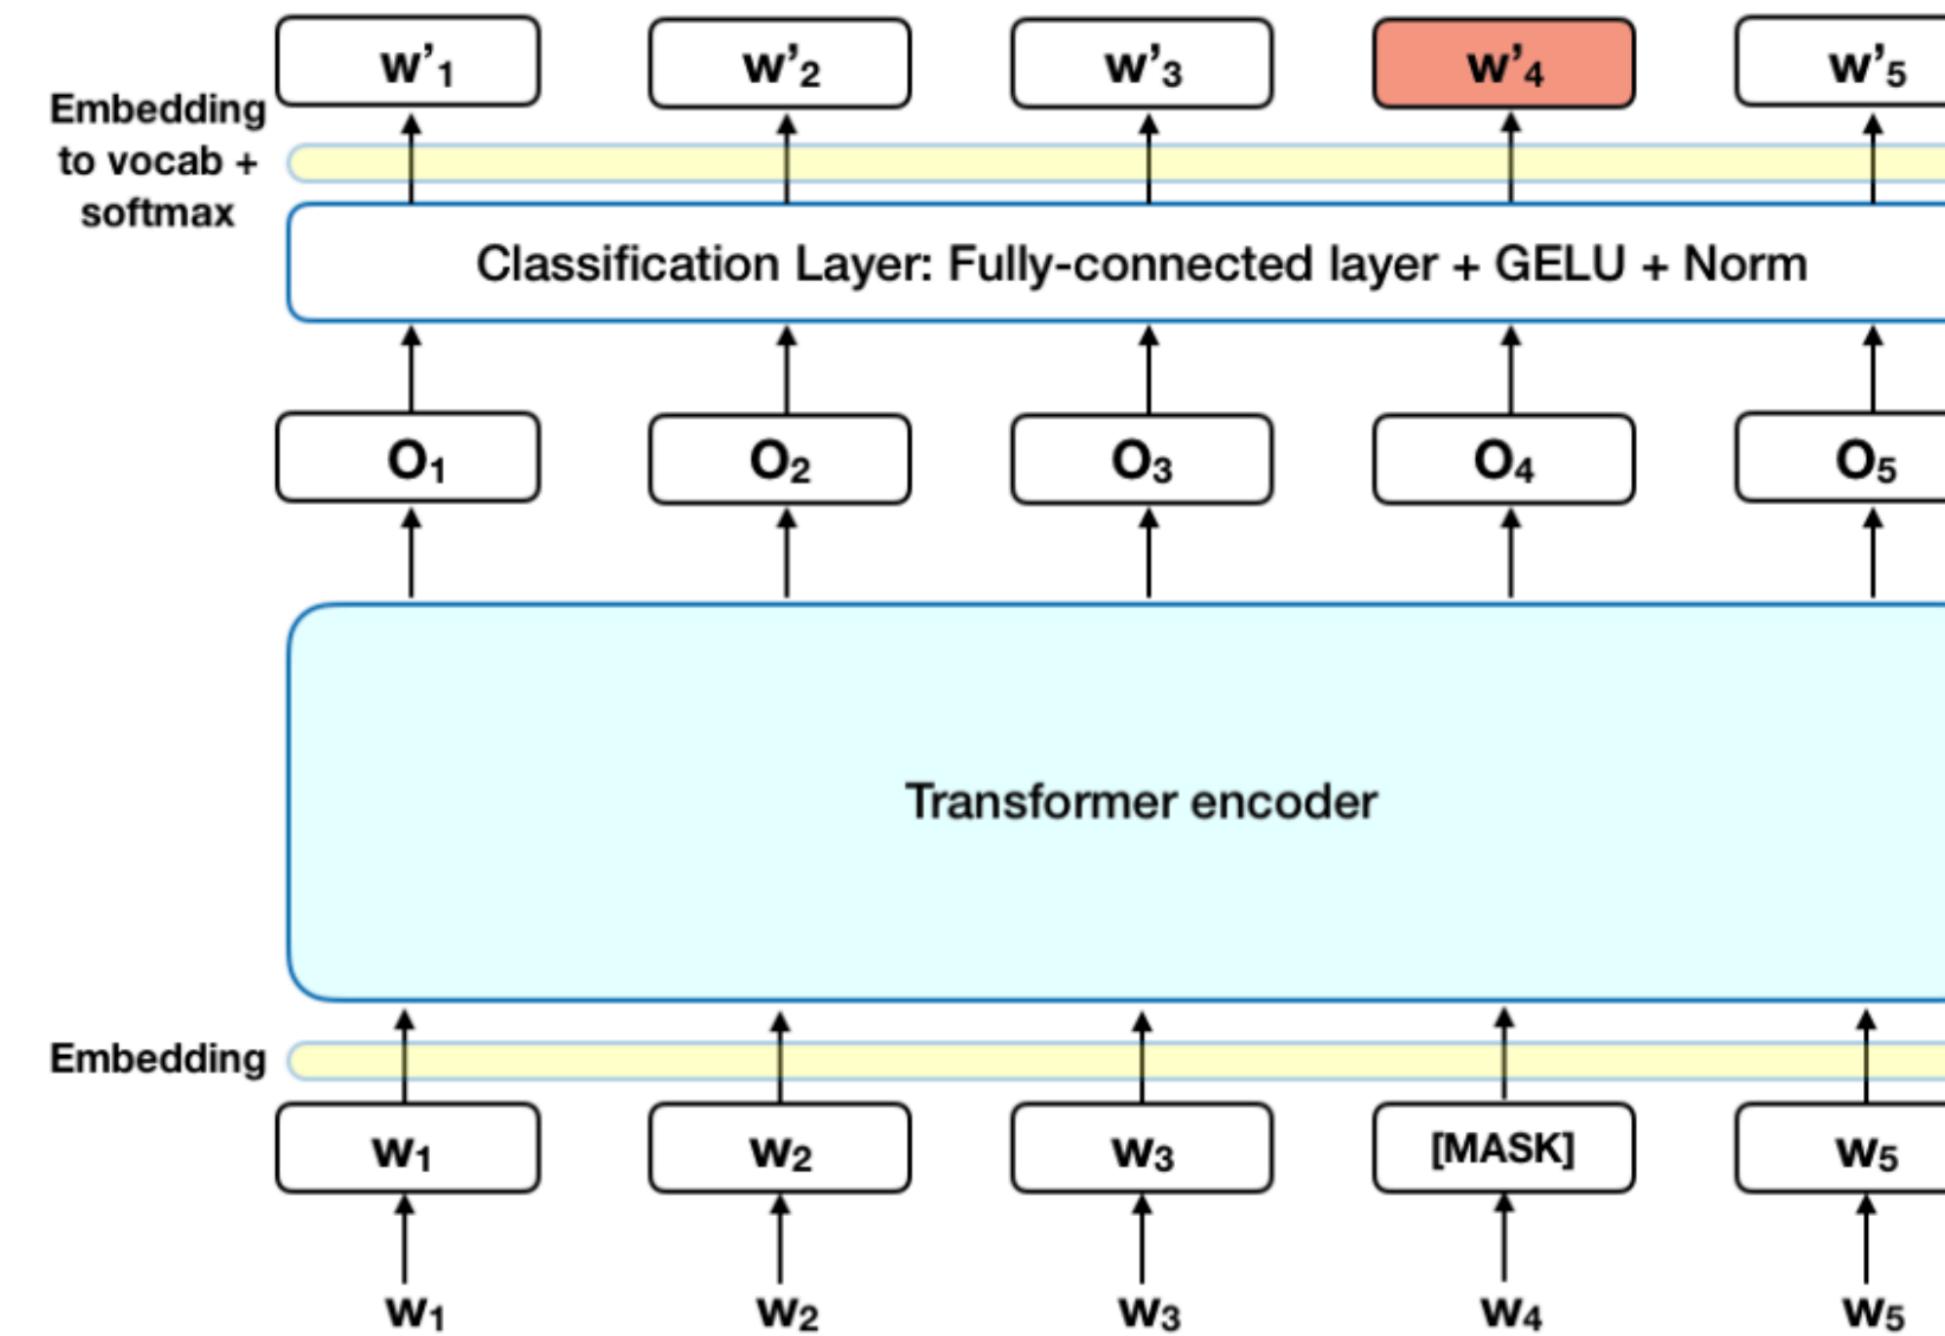

## BERT

- Key idea: replace LSTM by Transformer
- Define the generated pretraining task by masked language model
- Two pretraining tasks
- Finetune both BERT weights and task-dependent model weights for each task

# Contextual embedding

## BERT pretraining loss

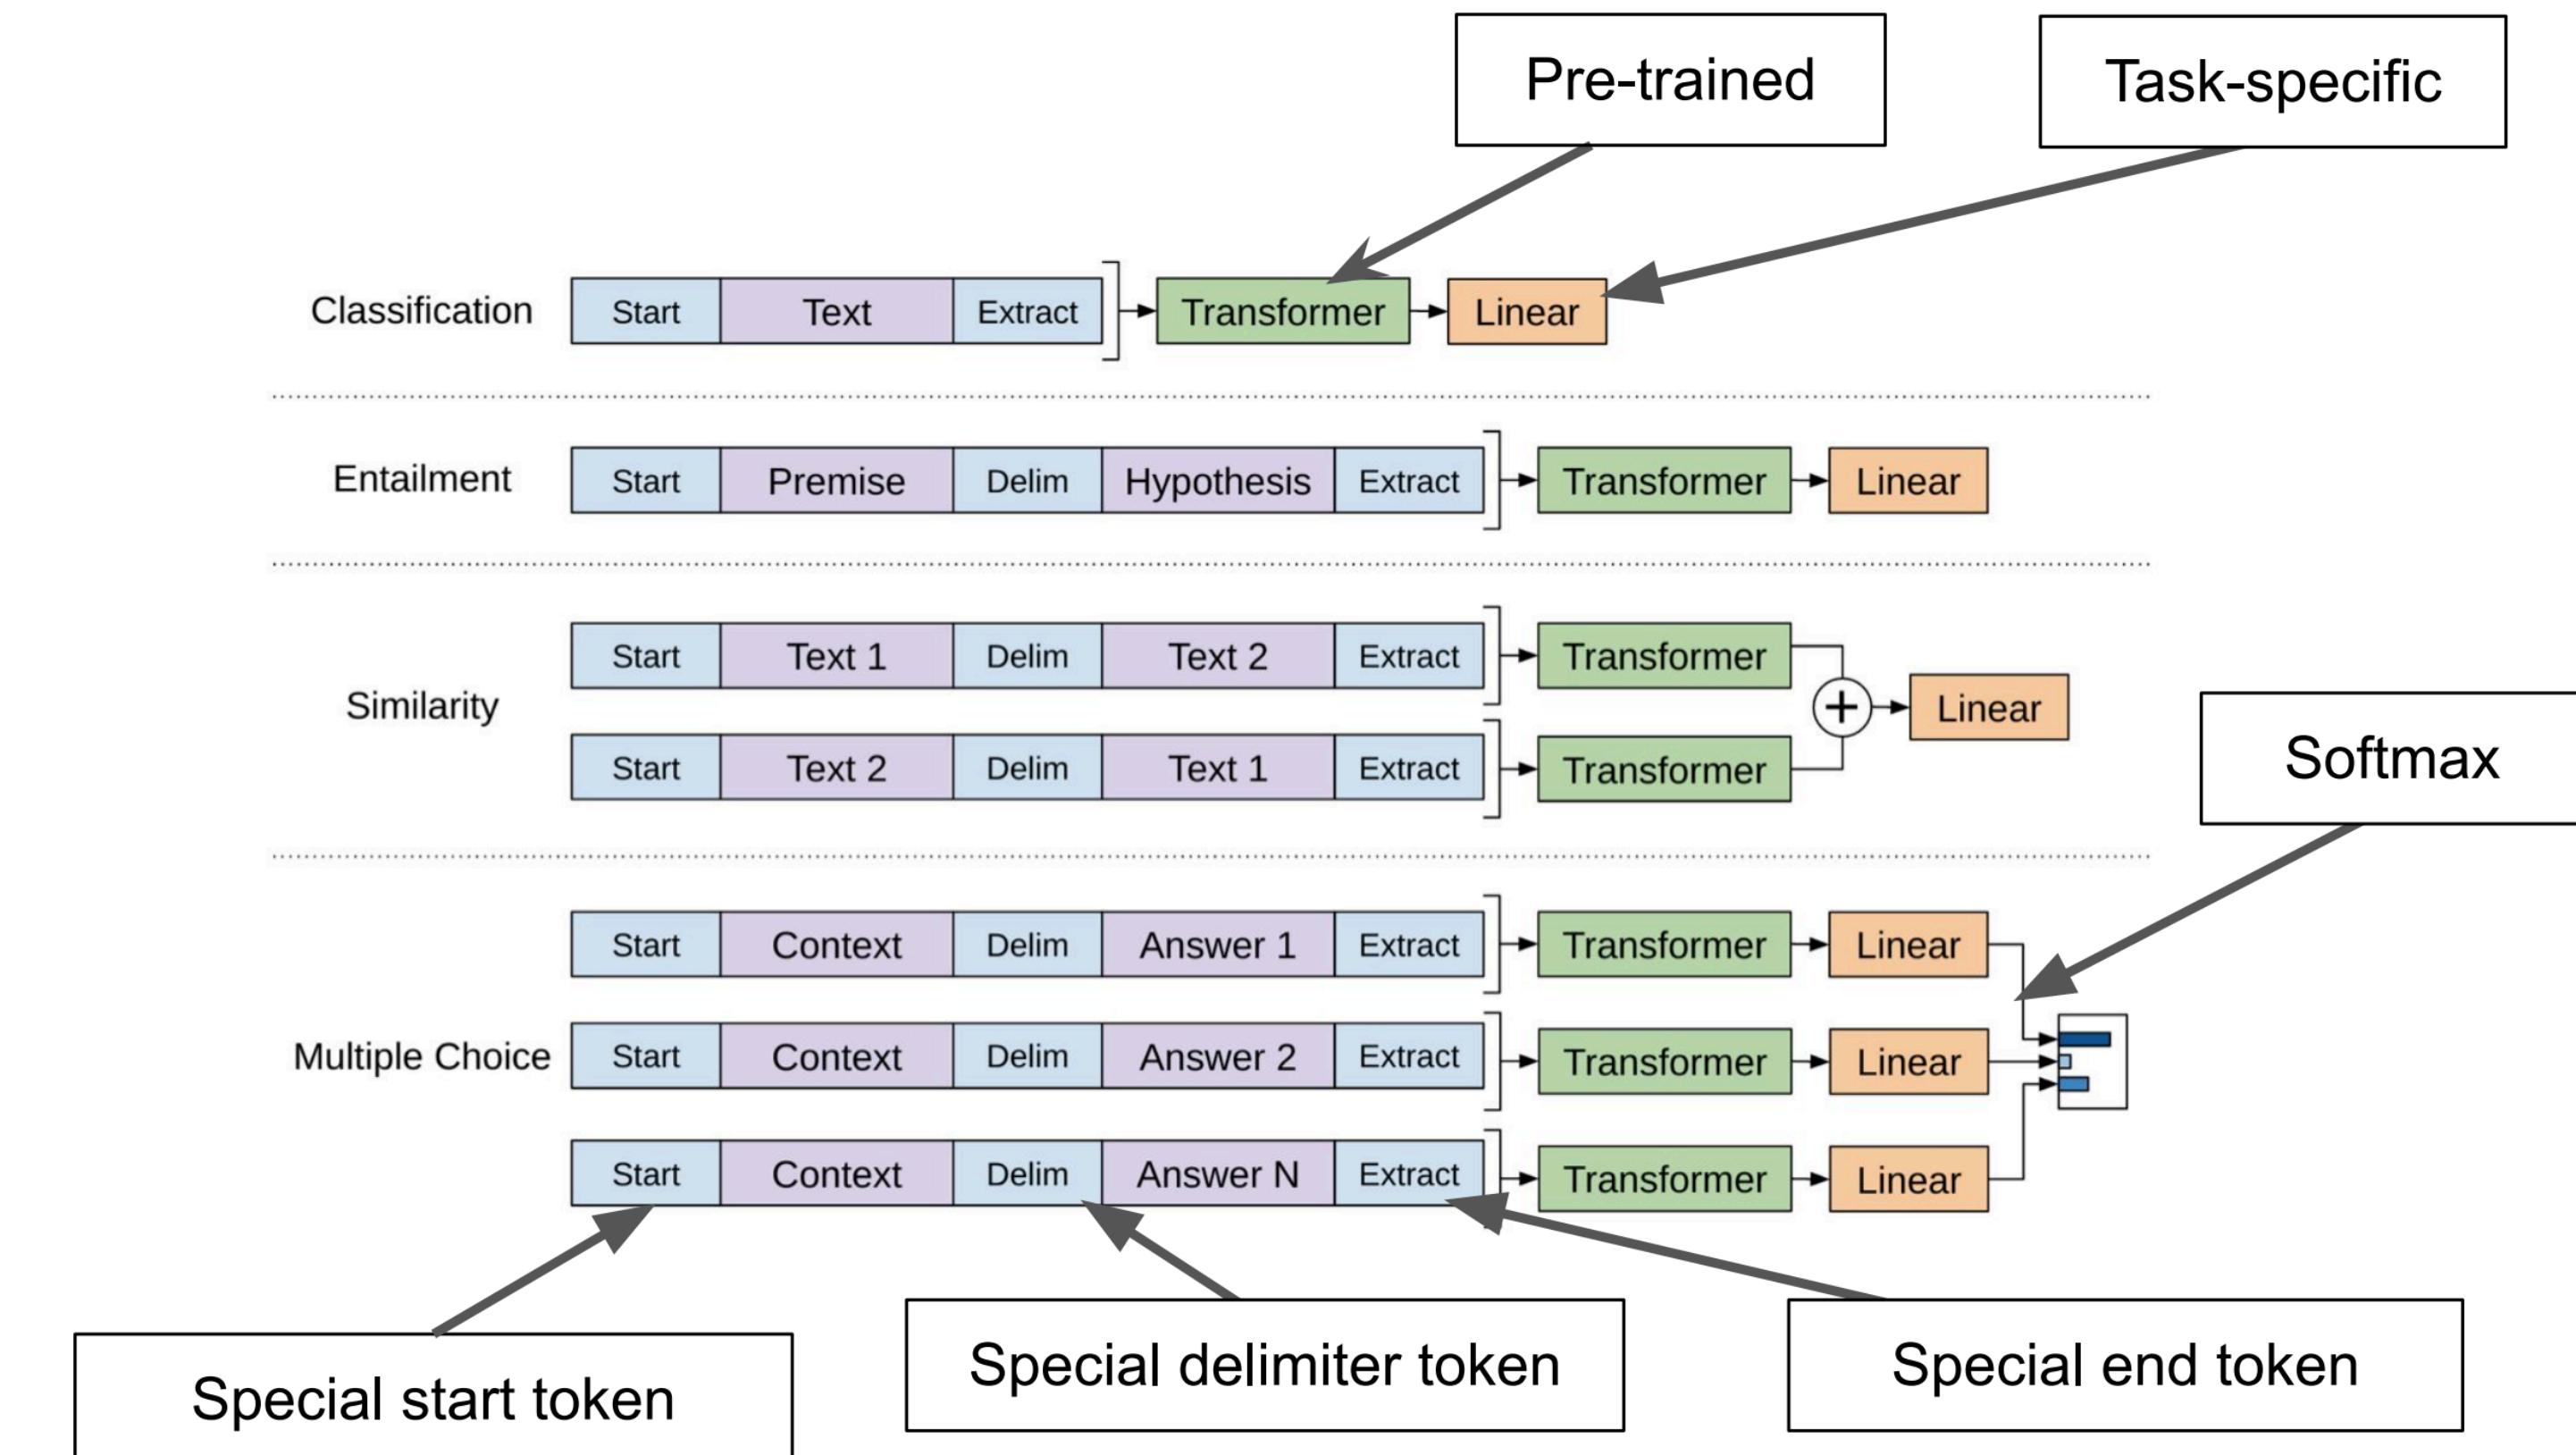

- Masked language model: predicting each word by the rest of sentence
- Next sentence prediction: the model receives pairs of sentences as input and learns to predict if the second sentence is the subsequent sentence in the original document.

# Contextual embedding

## BERT finetuning

- Keep the pretrained Transformers
- Replace or append a layer for the final task
- Train the whole model based on the task-dependent loss

# Contextual embedding

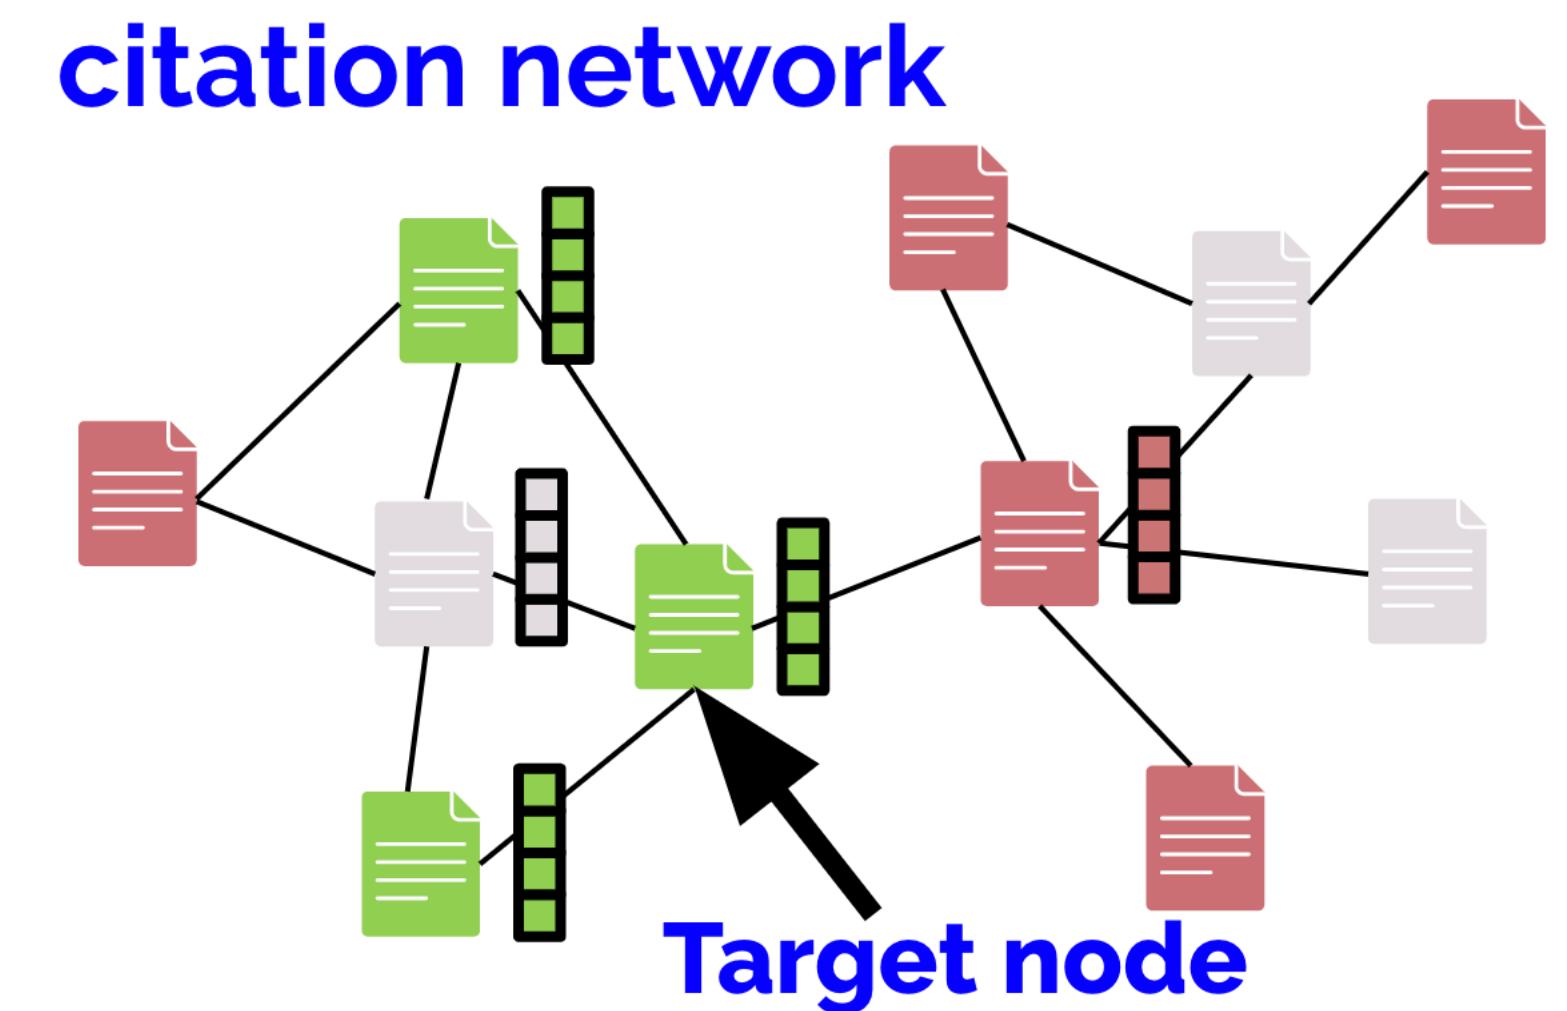

## BERT results

# Graph Convolutional Neural Network

## Node classification problem

- Given a graph of  $N$  nodes, with adjacency matrix  $A \in \mathbb{R}^{N \times N}$
- Each node is associated with a  $D$ -dimensional feature vector.
- $X \in \mathbb{R}^{N \times D}$ : each row corresponds to the feature vector of a node
- Observe labels for a subset of nodes:  $Y \in \mathbb{R}^{N \times L}$ , only observe a subset of rows, denoted by  $Y_S$
- Goal: Predict labels for unlabeled nodes (transductive setting) or
  - test nodes (inductive setting) or test graphs (inductive setting)

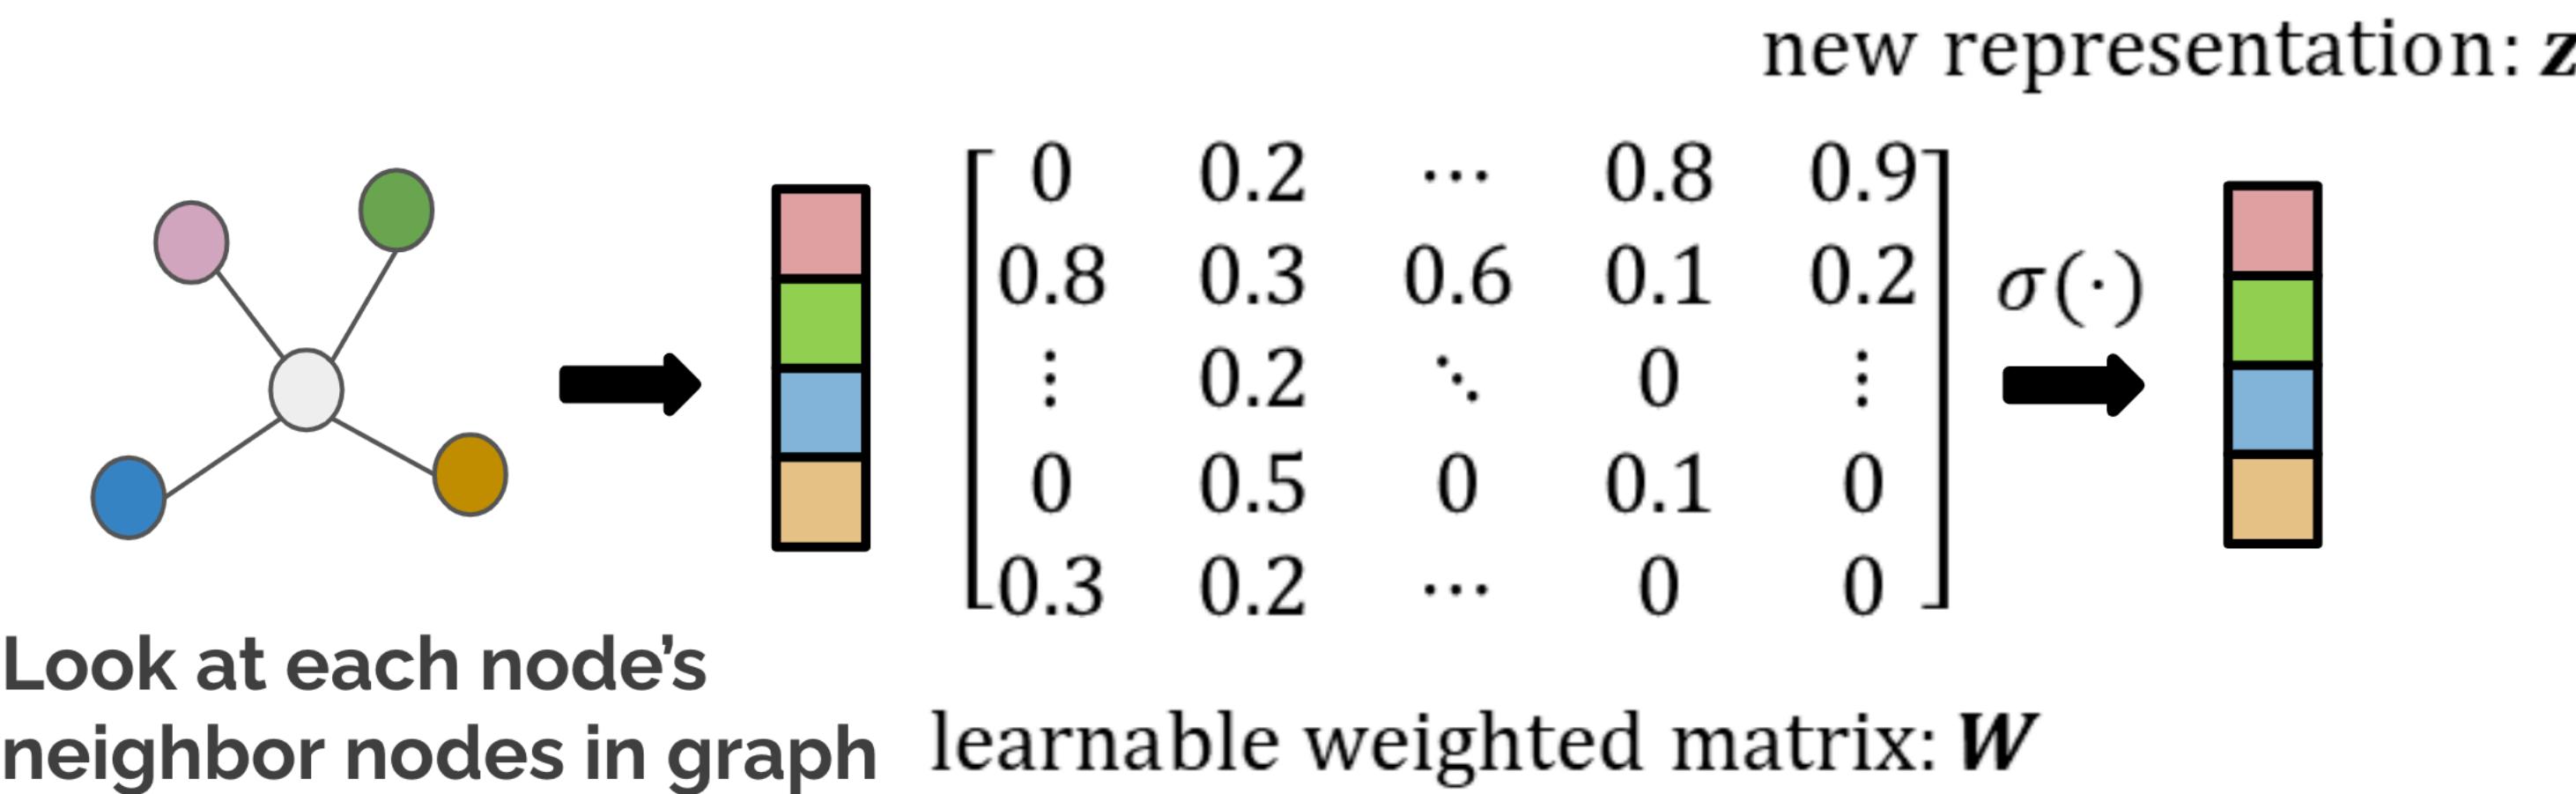

# Graph Convolutional Neural Network

## Graph Convolution Layer

- GCN: multiple graph convolution layers
- $\hat{A}$ : normalized version of  $A$ :
  - $\tilde{A} = A + I$ ,  $\tilde{D}_{uv} = \sum_v \tilde{A}_{uv}$ ,  $P = \tilde{D}^{-1}\hat{A}$
- Graph convolution:
  - Input: features for each node  $H^{(l)} \in \mathbb{R}^{n \times D}$
  - Output: features for each node  $H^{(l+1)}$  after gathering neighborhood information
  - Convolution:  $PH^{(l)}$ : Aggregate features from neighbors
  - Convolution + fully-connected layer + nonlinear activation:
    - $H^{(l+1)} = \sigma(PH^{(l)}W^{(l)})$ ,
    - $W^{(l)}$  is the weights for the linear layer
    - $\sigma(\cdot)$ : usually ReLU function

# Graph Convolutional Neural Network

## Graph convolutional network

# Graph Convolutional Neural Network

## Graph convolutional network

- Initial features  $H^{(0)} := X$
- For layer  $l = 0, \dots, L$ 
  - $Z^{(l+1)} = PH^{(l)}W^{(l)}, \quad H^{(l+1)} = \sigma(Z^{(l+1)}),$
- Use final layer feature  $H^{(L)} \in \mathbb{R}^{N \times K}$  for classification:
  - Loss  $= \frac{1}{|S|} \sum_{s \in S} \text{loss}(y_s, Z_s^{(L)})$
  - Each row of  $Z_s^{(L)}$  corresponds to the output score for each label
  - Cross-entropy loss for classification

# Graph Convolutional Neural Network

## Graph convolutional network

- Model parameters:  $W^{(1)}, \dots, W^{(L)}$
- Can be used to
  - Predict unlabeled nodes in the training set
  - Predict testing nodes (not in the training set)
  - Predict labels for a new graph
- Also, features extracted by GCN  $H^{(L)}$  is usually very useful for other tasks

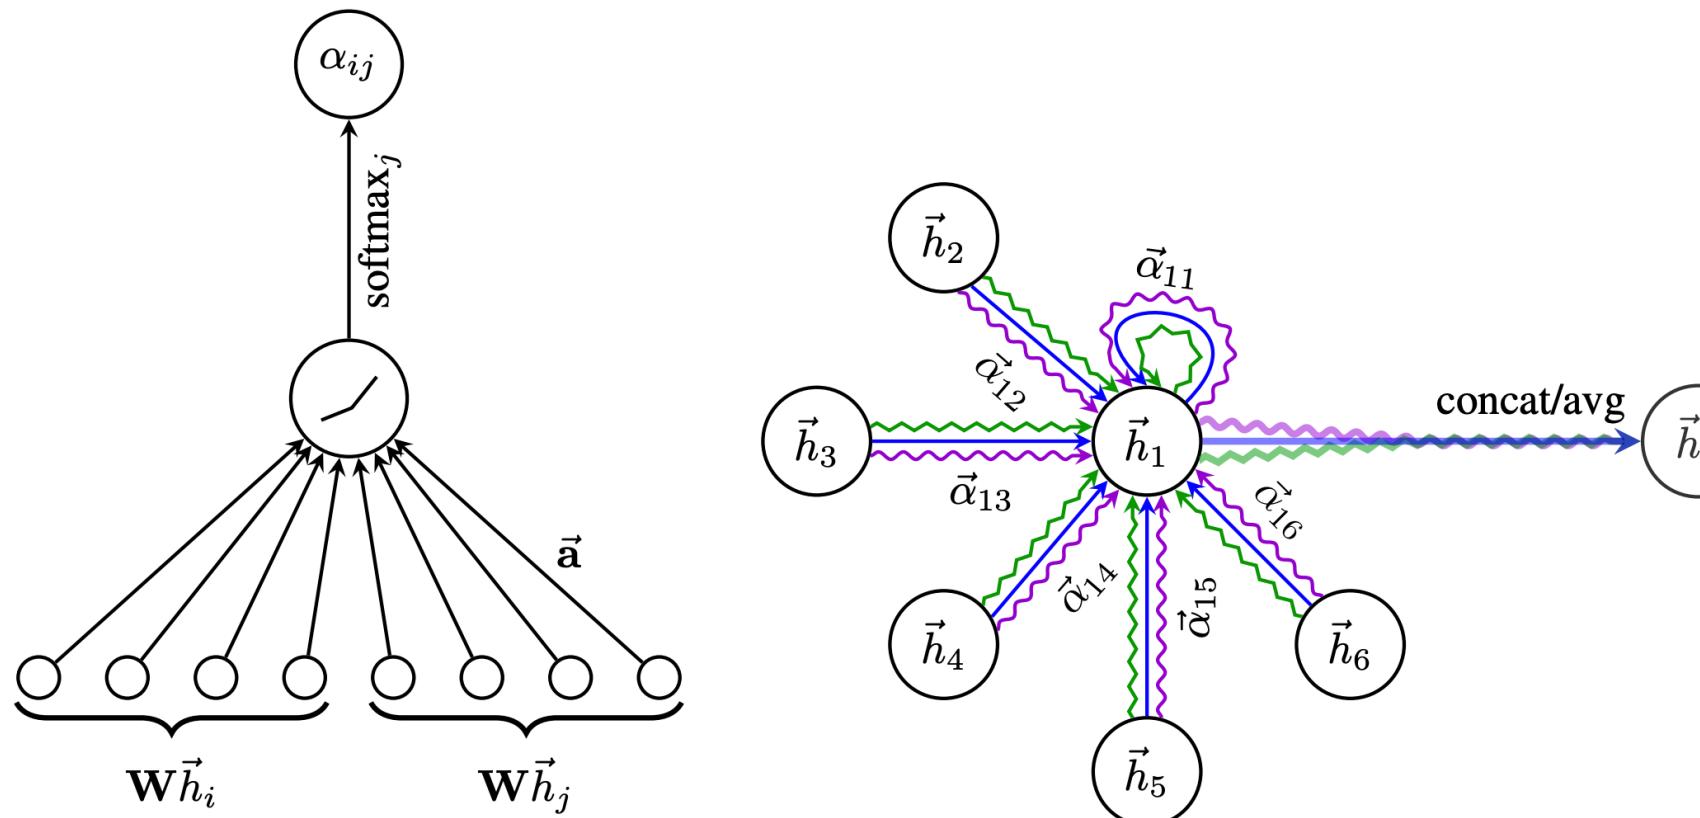

# Graph Convolutional Neural Network

## Graph Attention Networks

- Each edge may not contribute equally
- Using attention mechanism to automatically assign weights to each edge:

$$\alpha_{i,j} = \frac{\exp(\text{LeakyReLU}(a^T [W\vec{h}_i \mid W\vec{h}_j]))}{\sum_{k \in N_i} \exp(\text{LeakyReLU}(a^T [W\vec{h}_i \mid W\vec{h}_k]))}$$

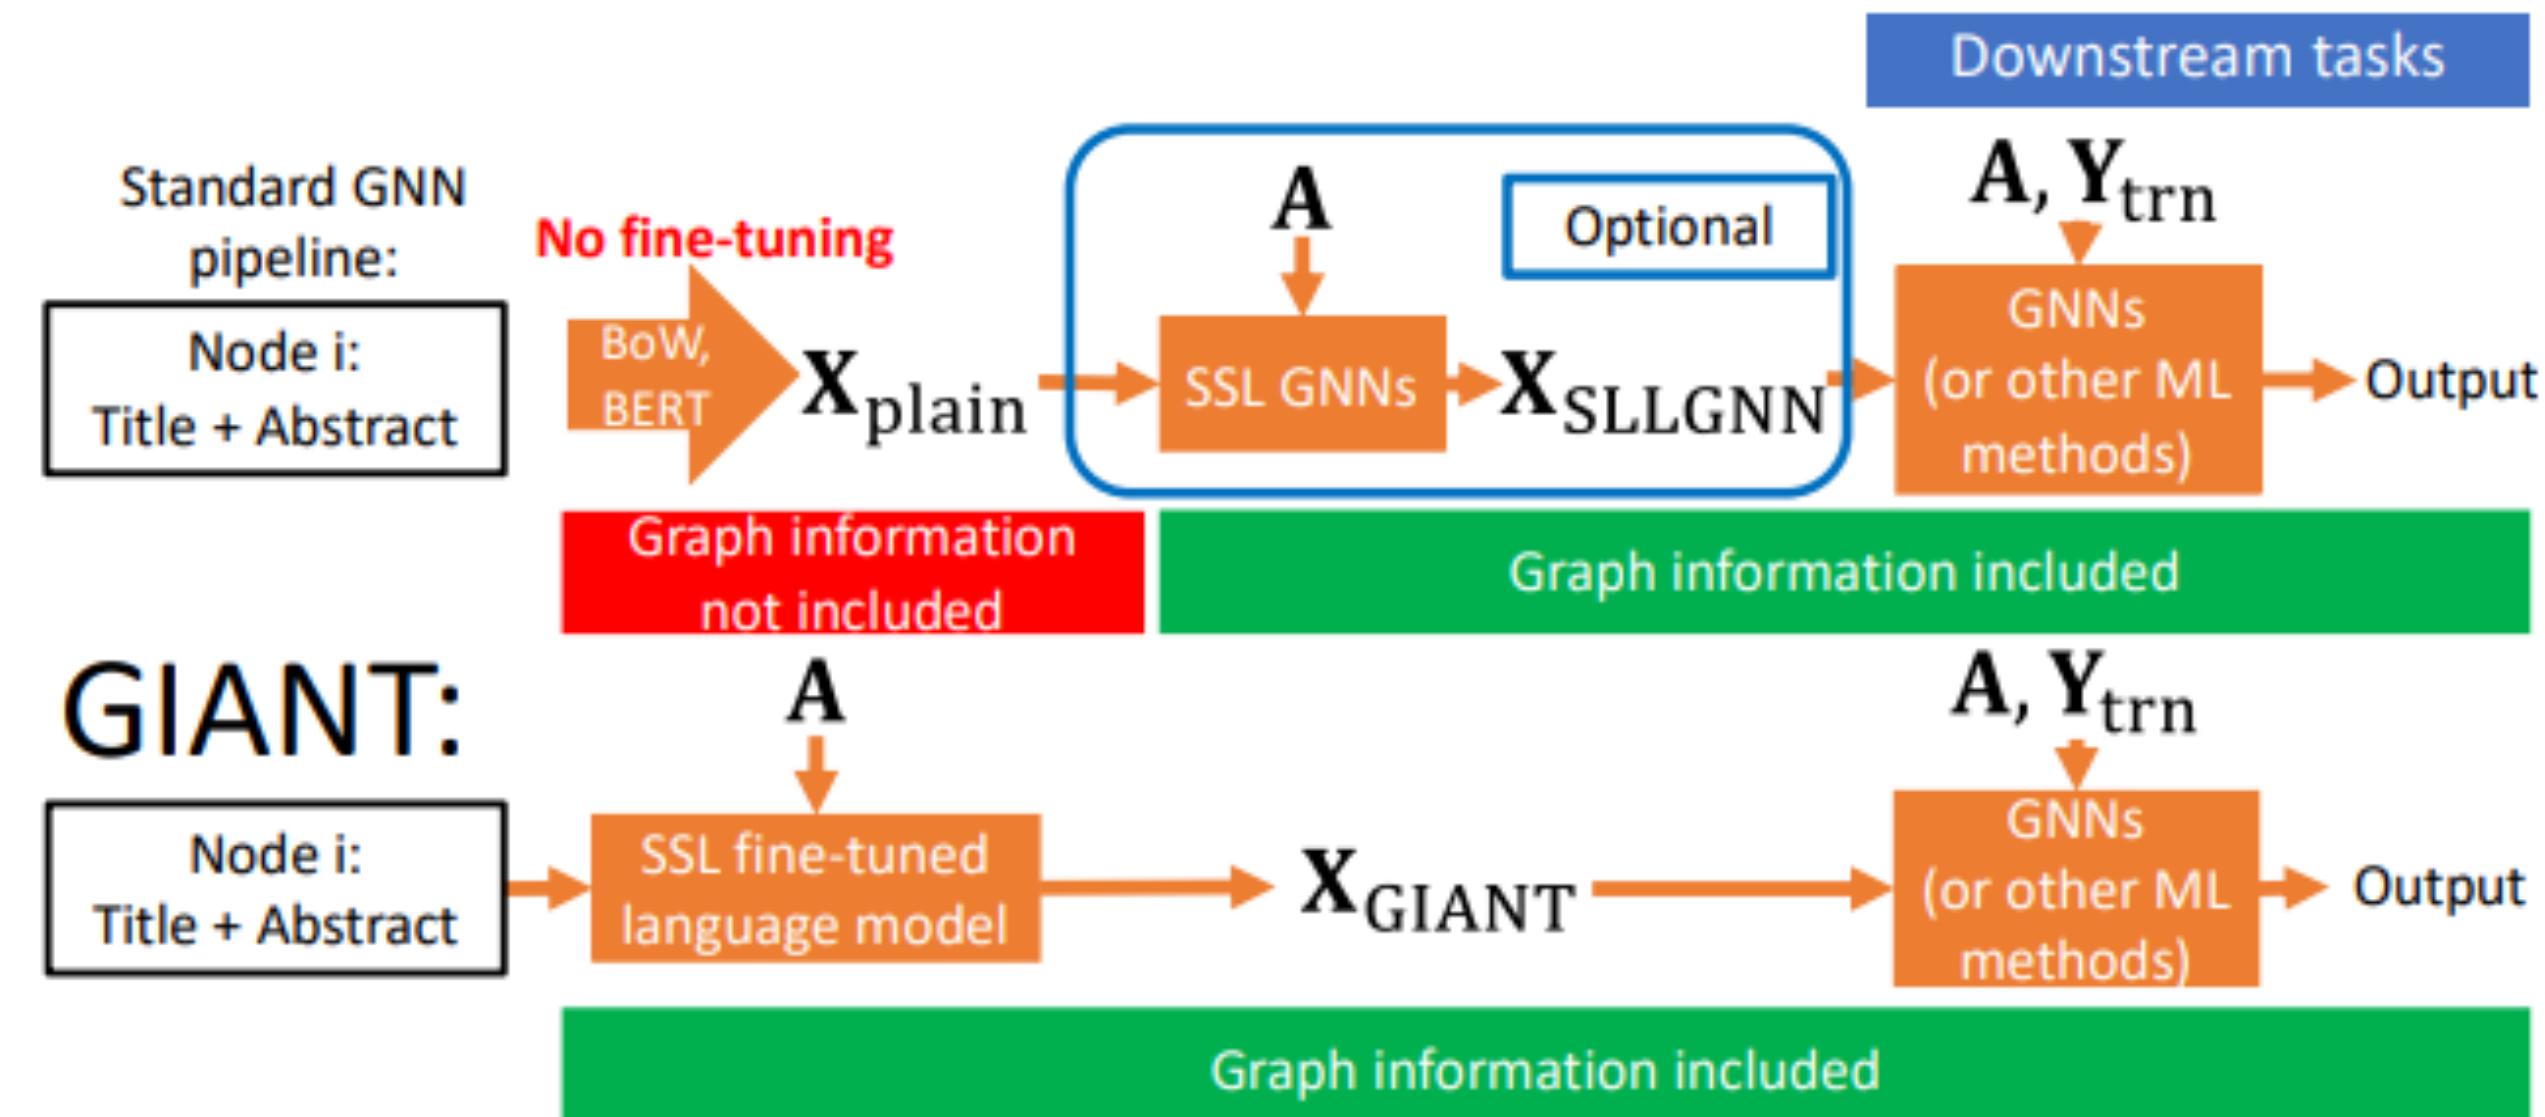

- where  $\vec{h}_i, \vec{h}_j$  are the features for node  $i$  and  $j$  at previous layer,  $W$  is the GNN weight,  $a$  is the additional learnable parameter for attention

# Graph Convolutional Neural Network

## GNN Pretraining

- Standard GNN pipeline:
  - Text features  $\Rightarrow$  BERT/Word2vec  $\Rightarrow$  GNN
  - GIANT-XRT: pretrain the feature extractors (e.g., BERT) based on the graph information.

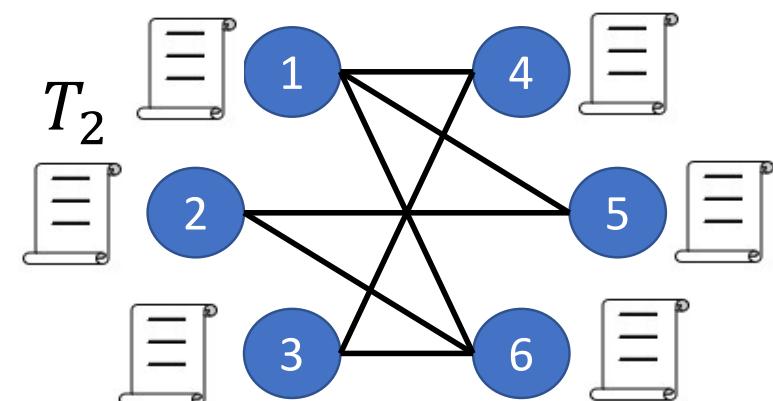

# Graph Convolutional Neural Network

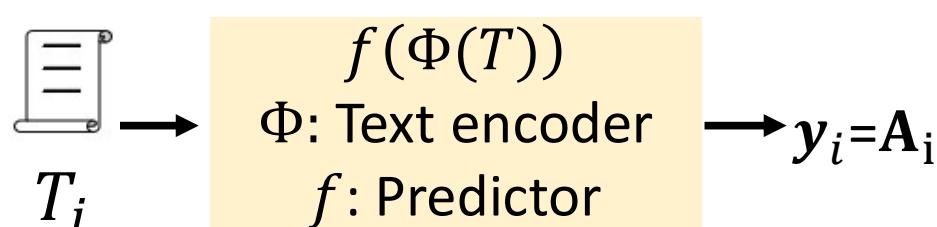

## GIANT-XRT

- Pretraining task: Predicting the **Neighbors** of each node
- Train BERT encoder to predict each row of adjacency matrix  $\Rightarrow$  Multilabel classification with huge number of labels

Neighborhood prediction as XMC problem:

$$\mathbf{A} = \begin{bmatrix} 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 \end{bmatrix} \quad \text{Multi-label } \mathbf{y}_2 \in \{0,1\}^n$$

# Graph Convolutional Neural Network

## GIANT-XRT

- State-of-the-art eXtreme Multilabel Classification (XMC) usually conducts multi-layer predictions.
- Example: PECOS, Parabel, ...
